GALOISIAN ALGEBRA.[1]

Lehrbuch der Algebra. Von Heinrich Weber. Zweiter Band. Pp. xvi + 796. (Braunschweig: Vieweg und Sohn, 1896.)

IN one of Mrs. Barbauld's stories a domestic fairy, with one touch of her wand, transforms a tangled heap of parti-coloured silk into an orderly array of neatly wound skeins. Not unlike this is the effect of group-theory upon mathematical analysis; and it has been truly said that, for some time to come, the progress of analysis will be approximately estimated by the advance in our knowledge of the constitution of groups.

We have, therefore, good reason to be grateful to Prof. Weber for the very clear and masterly exposition of group-theory which is contained in the first three books of his second volume. It may be that we have read it at the psychological moment; in any case, it seems to us the clearest and most interesting account of the subject that we have seen.

In the spirit of Cayley's *dictum* that a group is defined by the laws of combination of its symbols, the author begins by a perfectly abstract definition of a group, and develops the theory of its normal and other divisors, the composition of its parts, and a series of important theorems on the decomposition of a group and its associated indices. The first chapter concludes with a further and more general discussion of metacyclic groups, already introduced in Vol. i.

Chapter ii., on Abelian groups, is substantially a revised and improved version of the author's well-known memoir in the *Acta Mathematica*. The discussion of the characters of an Abelian group, in particular, seems to us much more easy to understand than the corresponding part of the original memoir. The most important results in this chapter are the existence of a basis; the isomorphism of groups with the same invariants; the fact that to every divisor of an Abelian group, of index j, corresponds a set of exactly j characters, which for all elements of the divisor have the common value 1, while for every other element of the group at least one of the characters has a value different from unity; and, finally, that every divisor is associated with a definite reciprocal group whose degree is equal to the index of the divisor.

The next chapter, which again reproduces, in great measure, Prof. Weber's original memoir, contains a complete discussion of the groups of a cyclotomic corpus. It is impossible to give a brief analysis of this very important chapter: it must suffice to say that a definite algorithm is given for determining all cyclotomic corpora which correspond to a given set of invariants, and for constructing the associated cyclotomic periods. Chapter iv. contains applications of the general theory to cubic and biquadratic corpora, and a proof that all Abelian corpora of the third and fourth degrees are cyclotomic. In other words, the roots of an Abelian cubic or biquadratic equation with rational integral coefficients may always be expressed as rational and integral functions of roots of unity. This is a special case of a very remarkable theorem of Kronecker's, first proved by Prof. Weber, and demonstrated later on in the present work.

Chapter v. contains a further discussion of groups in general, and brings the reader fairly abreast of contemporary research. The very real advance which has been made in this subject in recent years may be said to date from the publication of Sylow's fundamental theorem that if n is the degree of a group and p^α a power of a prime which divides n, the group contains a divisor of degree p^α. A very simple inductive proof (after Frobenius) is given in this chapter; and this is followed by a series of propositions, hardly less important, and more or less depending upon it. Then we have a remarkable theorem, due to Frobenius, that if the degree of a group is not divisible by a square, it must be metacyclic; and the other one, also discovered by Frobenius, that every group whose degree is $p^\alpha q$, where p and q are different primes, is metacyclic. These theorems dispose of most groups whose degrees do not exceed 100: the rest are separately discussed in § 34, where references are given to the recent papers of Cole, Hölder, and Moore. It may be remarked that English mathematicians are devoting a good deal of attention to group-theory at present: reference might well have been made to the work of Askwith and Burnside. The last article of this chapter contains a proof of the theorem that the permutation-group of n letters contains no transitive and primitive divisor of index not exceeding n, except the alternate group of index 2; a further exception being made for $n=4$, and for $n=6$ respectively. Although the proof given is, of course, perfectly sound, it does not seem the truly ideal one; and it may very well happen that in this, as in other similar cases, a more appropriate demonstration will be ultimately discovered.

Book II. deals with linear groups, and in particular with the polyhedral and congruence groups with which the researches of Klein have made us so familiar. The polyhedral groups are exhibited in an analytical form, which makes it comparatively easy to discern their subgroups; the proof that, besides the polyhedral groups, there are no other finite groups of the same type is after the manner of Gordon, and is remarkably simple in character. The decomposition of congruential groups (to a prime modulus) is effected very easily with the help of Galoisian imaginaries. The whole book may be profitably compared with the corresponding part of Klein's "Modulfunctionen," which, of course, traverses much the same ground.

Book III. contains various interesting applications of group-theory. The first chapter is on metacyclic equations, especially those of degree p^α, where p is a prime. It is shown that the Galoisian group of a primitive irreducible metacyclic equation of degree p^α is isomorphic with a linear congruence group (mod. p) of α variables; this group is compounded of a metacyclic group, isomorphous with

$$z'_i \equiv z_i + a_i \pmod{p},$$

and a *homogeneous* congruence group. Thus the problem of finding all such metacyclic equations is reduced to that of finding all the metacyclic divisors of the homogeneous congruence group. With the help of these

[1] The first volume of this work was reviewed in NATURE of November 12, 1896 (pp. 25–28).

results it is shown that all equations of the ninth degree with a linear congruence group are metacyclic, and a complete account is given of metacyclic equations of the degrees 4 and 8 respectively.

The next two chapters illustrate the power of group-theory in dealing with a certain class of problems in analytical geometry. The configuration of the inflexional tangents of a plane cubic, and the much more complicated configuration of the twenty-eight double tangents of a quartic, are here reduced to the scheme of a group. The advantage thus gained is twofold: a clear comprehension of the structure of the configuration, and the appropriate engine for attacking the algebraic problems which the geometry suggests. Thus (p. 389) the fact that the Galoisian group of the equation of the twenty-eight double tangents of a quartic is simple and doubly transitive, is intimately connected with the existence of Steiner's sets of six associated pairs of double tangents; and the structure of the group shows the exact nature of the algebraical problem which consists in the separate determination of these sets of lines.

Chapter xiii. deals with the solution of the general quintic equation. It is now well known that the general quintic cannot be solved by radicals, and that it has no resolvent of lower degree than the sixth. By the solution of the quintic is now understood either the expression of its roots by means of transcendental functions, such as elliptic or modular functions; or else the expression of its roots in terms of a definite algebraical irrationality, such as that furnished by the icosahedral equation. The chapter before us is chiefly concerned with the second method; it is shown that the equation

$$v^5 + 5av^3 + 5bv + c = 0$$

where a, b, c are any constants whatever, may be identified with one of the principal resolvents (Hauptresolventen) of the icosahedral equation of the sixtieth degree, usually written in the form

$$T^2 - zf^5 = 0.$$

The process of identification requires the determination of z and of two other auxiliary parameters λ, μ, which fix the particular resolvent to be chosen. If Δ is the discriminant of the given quintic, the three auxiliary parameters are expressible as rational functions of a, b, c and $\sqrt{5\Delta}$. Ultimately, then, the roots depend in a quite simple way upon those of the icosahedral equation; this latter, although of a high degree, is very convenient of application, because its Galoisian group is known, and its roots are algebraical functions of a single parameter (z). Moreover, one of its roots may be simply expressed by means of the hypergeometric series (see p. 432). From this point of view then, if the solution of numerical quintics were a matter of practical importance, we should construct a single-entry table of the values of the icosahedral irrationality for different values of z, and then make use, in each particular case, of the formulæ of identification above referred to.

Chapters xiv. and xv. contain a theory of ternary groups of substitutions, and deal in particular with a group isomorphous with the G_{168}, which may be otherwise represented as a congruence-group, mod. 7. This admits of a very interesting application to a special class of equations of the seventh order, analogous to the use of the icosahedral equation in solving the quintic.

The fourth, and concluding, Book is on algebraical numbers; and to those whose predilections are arithmetical this will probably prove the most interesting of all. When Kummer generalised Gauss's theory of complex integers by introducing complex roots of unity of any order, he was at first baffled by the perplexing fact that in certain cases complex integers presented themselves which were incapable of resolution into factors, and yet did not possess all the essential qualities of prime factors; thus, for instance, one and the same number might be expressible both as $\alpha\beta$ and as $\gamma\delta$, where α and β were integers essentially distinct from γ and δ, and yet $\alpha, \beta, \gamma, \delta$ were all indecomposible. By a stroke of unsurpassed genius, Kummer devised a theory of ideal primes, which at once removed the difficulty, and enlarged the province of arithmetic indefinitely. The divisibility of one real complex integer by another may be expressed by a series of linear congruences: Kummer succeeded in showing that, associated with every cyclotomic corpus, there are certain sets of congruential conditions which are precisely analogous in the general theory to divisibility by different primes in ordinary rational arithmetic. The satisfaction of one of these sets of congruences *may* denote divisibility by an actual (complex) prime; but whether this is so or not, the nature of the limitation thus imposed is just the same, and so, when the actual prime divisor does not exist, we say that the satisfaction of the congruential conditions expresses the existence of an *ideal* prime factor. As an example of how ordinary divisibility may be expressed by congruential conditions, we may take

$$ax + by \equiv 0,\ bx - ay \equiv 0 \pmod{a^2 + b^2}$$

which, if satisfied simultaneously, are equivalent to the divisibility of $x + yi$ by $a + bi$. Here, of course, when the congruences are satisfied, the complex factor $a + bi$ actually exists; but the congruences may be discussed, and their arithmetical significance developed, quite independently of this fact.

Kummer actually succeeded in showing how to construct, for any given cyclotomic corpus, the congruential conditions associated with the actual or ideal primes contained in it; but when his theory is extended to general algebraic corpora, it becomes impracticable to carry out the investigation precisely on Kummer's lines. The fundamental idea remains the same; and by an appropriate modification at the outset, Dedekind and Kronecker each succeeded in constructing an arithmetical theory capable of application to any corpus of algebraical integers whatever.

Their methods are not so different as at first sigh they may appear; this may be shown by an example which illustrates a fundamental point of the theory. Suppose that α and β are two ordinary rational integers; then the linear form $x\alpha + y\beta$, in which x, y assume all rational integral values, comprises a certain set of rational integers, and these are, in fact, the multiples of the greatest common measure of α and β. Thus, since a rational integer is given when all its multiples are given, we may say that the greatest common measure of α and β is represented by the linear form $x\alpha + y\beta$, or by the

series of integers comprised in that form. Now this notion may be extended to the case when α and β are any two algebraical integers belonging to the same corpus; and the extension may be made in two ways. In Dedekind's theory x and y, as before, stand for rational integers, and our attention is directed not so much to the form $x\alpha + y\beta$ as to the series of numbers it represents. This series is called an ideal, and denoted by $[\alpha, \beta]$; so far as α and β are concerned, it is found to possess properties precisely analogous to those of the greatest common measure. Kronecker, on the other hand, keeps the form $x\alpha + y\beta$ explicitly, using x, y as mere symbols, or umbræ; and the highest common divisor of α and β is defined as follows. The norm of $x\alpha + y\beta$ is a rational homogeneous form in x, y which is the product of a rational integer and a primitive form F; by the highest common divisor of α and β we mean $(x\alpha + y\beta)/F$. This definition has, of course, to be subsequently justified.

In a certain sense, then, the difference between the two methods is merely one of symbolic; but as in other similar cases (*e.g.* the methods of Cartesian and of homogeneous coordinates), it sometimes happens that propositions which are easily proved by the one are difficult for the other, and *vice versa*. Kronecker's theory was not worked out in detail in his famous "Festschrift"; Prof. Weber has now made it easily intelligible by adopting it, with some modification, as the basis of his exposition. Simplicity is gained by omitting primitive forms, such as F above, in the expression for divisors; and by means of a few new terms, such as "functional," the discussion is made at once concise and clear.

It should be added that the reader will find in this book not only a thorough account of the elements of the subject from Kronecker's point of view, but a guide to its most recent developments. Thus, for instance, it contains Minkowski's theorem on the minimum values of quadratic forms, with important applications to minimum representatives of ideal classes; and a summary of Hensel's very important investigations, by which it becomes possible to give an *explicit* representation of the prime ideals (or functionals) which belong to a given corpus.

Chapter xx., on quadratic corpora, shows the relation of Gauss's theory of quadratic forms to the general theory. Chapters xxi.–xxiv. are devoted mainly to the proof of Kronecker's theorem that all Abelian numerical corpora are cyclotomic; in other words, that the roots of *all* Abelian equations with rational integral coefficients are rational functions of roots of unity. The proof of this involves a long series of propositions, many of which are extremely valuable in themselves; we may instance the determination of the number of classes belonging to a given corpus, and the corollary that in every algebraical corpus there are an infinite number of prime ideals of the first degree. Perhaps the proof of Kronecker's theorem may some day be attained by a less laborious route; meanwhile it is a remarkable example of those arithmetical truths which are easily stated and easily understood, but, as yet, require for their demonstration an elaborate mathematical apparatus.

Prof. Weber's concluding chapter (xxv.), on transcendental numbers, contains a proof of the transcendence of e and π, and forms an elegant *coronis* for a work which is so important and so original that it is, to a great extent, above the range of ordinary criticism. As an introduction to, and exposition of, the theory of rational algebra and its arithmetical applications, it is simply invaluable. A student of real capacity, familiar with the technique of elementary algebra, may, by reading this work, together with Dedekind's wonderful tracts ("Ueber Stetigkeit," &c., and "Was sind u. was sollen die Zahlen?") and the last two editions of Dirichlet's "Zahlentheorie," equip himself for exploration in that strange unearthly region of arithmetic which attracts some sedentary spirits in much the same way as Arctic travel charms a Franklin or a Nansen. And even though he may not be one of the few who make discoveries of real importance, he will at least be able to appreciate intelligently the work that has been done, and the progress that has been made in developing the most abstract part of the only science that deserves to be called exact.

Gratitude has been defined by some practical cynic as the expectation of benefits to come: we must plead guilty to some such feeling on reading Prof. Weber's promise of a sequel, which is to deal with applications of the theory of algebraical numbers to the theory of elliptic functions; an application already partially carried out in his "Elliptische Functionen und algebraische Zahlen." And we cannot help remembering that, in conjunction with Prof. Dedekind, Prof. Weber has laid the foundations of a thoroughly arithmetical treatment of algebraic functions of one variable, in which alone (in our opinion) will be found a complete justification of the results to which Riemann was led by his geometrical method. Is it too much to hope that Prof. Weber may sometime be willing to develop these principles into a treatise on algebraical and Abelian functions? G. B. M.

THE WORSHIP OF TREES.

The Sacred Tree; or, the Tree in Religion and Myth. By Mrs. J. H. Philpot. Pp. xvi + 179. (London: Macmillan and Co., Ltd., 1897.)

THE further we are able to penetrate the mists which hang over the early history of mankind, the more sure we become that the primeval ancestors of our race regarded certain trees with veneration and awe; and it seems quite possible that in the earliest times the tree was a symbol of a supernatural and almighty power, which we might describe by the word "god." We shall not attempt to express in years the amount of the time which must have passed since tree worship began; but it will be sufficient, in the course of this short notice, to give a few proofs of its existence in the times which antedate the literature and history of all countries except those of Egypt and Southern Babylonia.

The study of the tree in its relation to religion and myth has occupied the minds of some of our best anthropologists, and though we are inclined to think that presently certain people will find the tree in every ancient piece of work and symbol—just as some investigators find the Christian cross everywhere, and others find the lotus in every ornament—still there is no

doubt that nearly every nation belonging to the ancient civilised world has connected trees with its objects of veneration; and many folk have openly admitted that they regarded them as holy things, and that, in consequence, they have performed sacred rites and ceremonies beneath and near them. Many interesting details of the subject have been collected by such indefatigable investigators as Prof. E. B. Tylor, Mr. Frazer, and the late Prof. Robertson Smith; but, as far as we remember, no one before Mrs. Philpot has taken the pains to reduce the commoner facts to a simple straightforward narrative such as she gives in the volume before us. Here we have in nine chapters a brief sketch of tree worship, which begins in times almost prehistoric, when the suppliant knelt in terror before the solitary tree or in the forest, and ends with the Christmas-tree round which children and adults gather joyfully.

To illustrate her points Mrs. Philpot introduces several well-chosen drawings, and a somewhat meagre index ends the book. It is evident that Mrs. Philpot's work is intended for all such as have not made a special study of tree-lore, and to them her little treatise will be of the greatest value; for, apart from the general accuracy of her facts, her story is told with a directness which, to say the least of it, is time-saving. Her references are, however, either too many or too few; personally we should have liked them to be increased in number, for when a reader likes a book, and is told in it where to go for further information, he sometimes goes, and thus knowledge is spread, and more people are induced to take an interest in that particular subject. On certain points, too, Mrs. Philpot might have given us more information with little increased labour. Thus, in speaking of tree worship in Babylonia (p. 7), we might with advantage have been told that Rim-Sin, a king of Babylonia about B.C. 2300, calls himself "magician of the holy tree of Eridu," and also that a cuneiform inscription actually describes this tree "with its root of crystal which stretcheth to the abyss." On p. 10, the "sacred tree of Heliopolis," of which Mrs. Philpot speaks, is, of course, the famous Persea tree near which the Cat (*i.e.* the Sun) slew the serpent of darkness; both Cat and Tree are depicted in the vignette which accompanies the seventeenth chapter of the "Book of the Dead." In the same city, too, flourished the famous olive tree which is mentioned in the text of the pyramid of Unas (line 70), inscribed about B.C. 3500. The Tamarisk tree (*Aser*), which is mentioned in the forty-second chapter, and the Cedar tree, which plays such an important part in the "Tale of the Two Brothers," should also have been noticed. In some cases a little more information might well have been given to the reader. Thus, the Arabs believed that the Tûbâ tree (see p. 132) was specially created by God along with the Throne, and the Garden of Eden, and Adam; this statement is important, for it shows that the Muhammedans could not imagine Paradise without a tree.

The account of Alexander's visit to the trees of the Sun and Moon in India, not Persia, should have been taken from Alexander's letter to Aristotle as given in Pseudo-Callisthenes (ed. Müller, Book iii.), for the Persian translation, or rather version, modifies a great deal of it, and omits many important points. On the great trees of India and Africa the histories of Masûdî (ii. 81-83) and Ibn-Batuta (iv. 391 f.)—both available in good French translations—might have been consulted, and Mrs. Philpot would have derived scores of valuable hints about trees and their worship from Yule's edition of "Ser Marco Polo," vol. i. (2nd ed.). The four cross-bars of the Tet-pillar (p. 117) are in reality four pillars, of which only the tops are seen, and these represent the four cardinal points; the late Mr. O'Neill's "Night of the Gods" contains many facts relating to the universe-tree or pillar. The pillar which joins the two paradises (p. 132) is not called "strength of the Hill of Sion," but "foundation (*mĕkhôn*) of the Hill of Sion." Among proofs of the beliefs in the existence of a "tree of life" at a very early period may be mentioned one which occurs in the text of the pyramid of Pepi I., where we read that the deceased goes to the great lake round which the gods sit, and that they give him to eat of the tree of life upon which they themselves do live; now these words were inscribed about B.C. 3500, and it is more than probable that they were first written many, many centuries before that date.

We do not call attention to these facts from any wish to find fault, but only to indicate the sources whence Mrs. Philpot may derive additional information when a second edition of her book is called for. We believe that her book will be read with pleasure by many, but it would greatly help the general reader to give him definite facts and figures which he could remember and think upon after he has closed the book.

OUR BOOK SHELF.

Relics of Primeval Life. By Sir J. William Dawson, K.C.M.G., F.R.S. Pp. xiv + 336. (London: Hodder and Stoughton, 1897.)

FOR more than thirty-five years *Eozoon Canadense* has been before geologists, and the evidence brought forward in support of its organic nature, and against it, has been sufficient to enable people competent to judge the question to arrive at a firm conclusion one way or the other. The case for Eozoon as a Laurentian fossil is stated by Sir William Dawson in this volume, and the observation of similar characteristics in decidedly mineral structures is either ingeniously explained, or the resemblance is declared to be illusory. The work represents the substance of a course of lectures on Pre-Cambrian fossils, delivered in the Lowell Institute, Boston, and will be read as much for the account it contains of early animal life, as for the debatable matters with which it deals.

The True Grasses. By Eduard Hackel. Translated from "Die Natürlichen Pflanzenfamilien" by F. Lamson-Scribner and Effie A. Southworth. Pp. 228. 8vo, with 110 illustrations in the text. (Westminster: Archibald Constable and Co., 1896.)

THIS appears to be a very good translation of a work which does not materially differ from Bentham and Hooker's "Genera Plantarum," except that the diagnoses are much briefer, though, on the other hand, they are supplemented by some figures which, by the way, are printed much too black. What part Effie Southworth took in the translation is not apparent, for the preface is signed by F. Lamson-Scribner, dating from the University of Tennessee, without any mention of the former. In fact, the book was first published in America. It is important to state that some botanical knowledge is necessary to enable a person to use the book, and also that, with the exception of the cereals and a few others only the genera

are dealt with. Of these there are upwards of 300, and a rough estimate of the total number of species in the world puts them at 3000. Prof. Hackel is a well-known and accepted authority on this difficult family, so that the translation will be welcome to those botanists who are not familiar with either Latin or German. The introductory chapter on the structure, morphology and physiology of grasses enhances the value of this little book.

It may be of interest to add, in this connection, that the grasses of British India, described in Sir Joseph Hooker's voluminous "Flora," just completed, number 850 species belonging to about 150 genera!

W. B. H.

The New Poultry Guide for British Farmers and Others. By Kinard B. Baghot-De la Bere. Pp. 65. (London: Seeley and Co., Ltd., 1897.)

THIS book is addressed to small landowners and tenant farmers of Great Britain. It is a concise and practical guide to the selection and keeping of poultry for profit. Written by one who has had a wide experience, the book should appeal forcibly to the distressful agriculturist, and make him start a poultry farm at once

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Liquefaction of Air by Self-intensive Refrigeration.

FROM a recently published paper by Dr. Carl Linde, on the above subject, it appears that in his most successful attempt without the use of auxiliary refrigeration, he was able, with a copper-tube apparatus weighing 132 lbs., to liquefy air in two hours, with an average higher pressure of 190 atmospheres.

It will be of interest to those who have followed this subject to hear of the latest performance, which constitutes a great advance on the above results; the weight of the copper coil having been reduced to less than one-sixth, the time required for liquefaction to less than one-fourth, and the pressure of the compressed air to less than one-half.

An apparatus which I designed on an improved plan, and which was completed in May 1896, was exhibited at work at the conversazione of the Royal Dublin Society held on the 10th inst.; and, the liquid being easily removable as produced, it supplied the material for repeated demonstrations during the evening, with the usual experiments.

Air at an average pressure of 87 atmospheres was supplied by a compressor lent by Messrs. Arthur Guinness, Son, and Co., which had been formerly used for compressing carbonic acid gas; and the compressed air was carried through 80 feet of copper pipe to the room in which the apparatus worked. No auxiliary cooling by carbonic acid or other agents was used to reduce the temperature of the compressed air before or after it reached the apparatus.

The copper tube in the exchanger, weighing only 20 lbs., was disposed in a special arrangement of coils, so that the temperature was exchanged over a range of 202° C. within 1½ of a degree, the compressed air entering at + 10° C., passing through the liquid state at − 192° C., and issuing a few seconds later at +8·6° C.

When a start was made with the apparatus at atmospheric temperature, the jet of liquid air was clearly seen in twenty-five minutes, and the liquid was collecting in the receiver in thirty-three minutes from the start. When the apparatus was cooled down by continuous working, the liquid began to collect again in two minutes after emptying the receiver, and accumulated at a good rate: the exact quantities of liquid and air for a given time have yet to be measured.

The receiver is a glass vessel protected by a vacuum of the kind invented by Mr. Crookes, first applied to refrigeration work by M. Cailletet, of Paris, and improved and popularised by Prof. Dewar. It is further protected by a special glass attachment fitted in such a way that the vacuum vessel can be readily removed without any risk of fracturing it by movement in contact with rubber hardened by cold to the rigidity of stone, and can be quickly replaced without interfering with the effective action of the apparatus.

The apparatus has been very strongly and neatly made by Brin's Oxygen Company, of Westminster, and tested to a very high pressure. It should be mentioned that in the almost impossible event of a joint giving way, no one can be hurt, since the high-pressure air exists only in the form of a thin column or thread with very small admission-passages. The harmlessness of a burst under these conditions has been practically demonstrated with a joint constructed in such a way as to burst inside a similar construction at 120 atmospheres, when the effect proved to be quite as mild as had been anticipated, and entirely harmless—a mere blowing-off.

This is the only apparatus existing in the United Kingdom which liquefies air without auxiliary refrigerating agents.

March 13. W. HAMPSON.

Patterns produced by Charged Conductors on Sensitive Plates.

IN your issue of January 21, 1897, Mr. James I'Anson publishes some coin photographs showing the effect of the brush discharge around the edge of the coins, and around the portions in high relief, and asks if any similar results have been obtained by others.

In the *Physical Review* (vol. ii. p. 59, 1893) is an article on electric photography, in which are published some similar photographs made by me in 1892 by exactly the same method described by Mr. I'Anson. The same method is also described by Prof. F. J. Smith, whose "Inductoscript" should be by this time well known in England. The rays from the discharge around the edge of the coin are plainly shown in one of my photographs in the *Physical Review*, and are commented upon in the article.

I also gave a photograph made by the same process when the coin was insulated from the photographic plate by a sheet of mica, and mentioned others made with the coin insulated from the plate by shellac, paraffin, and gutta-percha, which would seem to disprove Mr. I'Anson's theory that the brushes are due to electrified streams of air coming in contact with the sensitised plate.

During the past year, I have repeated these experiments with both the coin and the photographic plate carefully insulated and placed between the plates of a condenser attached to the discharging knobs of a large induction coil. I have made in this way photographs of coins, and other conductors, imbedded in the centre of a block of paraffin two centimetres thick, under which circumstances they could not send off streams of electrified air.

I have also repeated in this way some of the X-ray shadow effects by placing objects between the condenser plates and the photographic plate, to intercept the waves sent off from the condenser plates themselves. A good conductor placed near the photographic plate will regularly be photographed more strongly than the condenser plates, even though it be only one thickness of gold-leaf on glass; but if placed several centimetres from the photographic plate, and near one of the condenser plates, it may cast a shadow on the photographic plate. An insulator placed upon the photographic plate usually casts a shadow upon it, but in some cases insulators of high specific inductive capacity seemed more transparent than the air to the waves sent off from the condenser plates.

Since the oscillations in such a condenser field must correspond very closely in character with longitudinal waves in the ether, it seems probable that if X-rays are longitudinal ether waves, their wave-length must be very short; as, otherwise, they would induce waves in conductors similar to those induced in an alternating condenser field.

I enclose a photograph of two coins placed side by side on a sheet of mica which was laid upon the photographic plate. The whole was placed in a light-tight box, and inserted between the condenser plates, from which it was carefully insulated by large panes of heavy plate-glass. The condenser plates were 4·5 cm. apart, and a 5 cm. spark was passed between the discharging knobs of the coil for two minutes, after which the plate was taken out and developed in the usual manner. It was found later that an exposure of a few seconds gave equally good results

This photograph was selected for comparison with those of Mr. I'Anson because the rays are plainly shown, while the shadow of the mica sheet, which was between the coins and the photographic plate, can also be plainly seen. It will be noticed that the rays are most numerous between the coins.

FERNANDO SANFORD.

Stanford University, Cal., February 19.

[The photograph referred to by Mr. Sanford is similar to one which illustrated Mr. I'Anson's letter (p. 270), the chief difference being that a greater number of rays are shown in the space separating the two coins.—ED. NATURE.]

Laboratory Use of Acetylene.

IN your issue of September 3, 1896, appeared a short letter stating that acetylene was in use in our laboratory for blow-pipe work, and further stating that we hoped to introduce the gas on to the benches. From one or two inquiries received since then, it would seem that the fact of our now having succeeded in doing this will be of interest, as, indeed, it should be to any one possessing or contemplating the erection of a laboratory in the country where ordinary gas is costly or not obtainable. We use an ordinary Bunsen of special dimensions, the aperture of the jet being very small, and the tube (also of small diameter) is provided with a cap to protect the burner from dust when not in use. The generator is a modified form of one of those at present in the market, and gives between seven and eight inches water pressure. With six inches pressure a perfectly non-sooty flame of good size can be obtained, and a "quarter Bunsen flame" under as little as three and a half inches. If turned lower than this, the flame becomes luminous, the draught becoming insufficient. The flame is steady, noiseless, and, unless turned too low, evinces no tendency to strike down. The consumption of gas averages one cubic foot per burner per hour. The flame possesses, of course, great heating power, one volume of acetylene being for practical purposes nearly twice as effective as one volume of ordinary gas. This means an immense saving of time in all heating operations, and in many cases, such as small fusions and simple glass-working operations, we are able altogether to dispense with the blow-pipe; the burner alone supplying quite sufficient heat. Our installation has only just come into use, but, so far, has given us no trouble. We have used an acetylene blow-pipe for nearly a year, and have had no difficulties. The cocks and general fittings should be thoroughly good; any one who has not gone into the matter will be surprised to find what an indifferent article, as regards leakage, is the average gas-cock. It will be found that the cocks tend to work stiff, probably on account of the absorption of the acetylene by the lubricant, and it is much to be desired that the question of the most suitable lubricant should be investigated.

The Laboratory, Felsted School, Essex. A. E. MUNBY.

Immunity from Snake-bites.

IN case any of your readers may be working on the subject suggested by Mr. Dawson Williams in NATURE, March 4, page 415, that mosquitoes may be the carriers of pathogenic microbes, I send you the following.

In a town in the interior of Asia Minor, where I resided some years, and where malarial fever was at all times very common, I frequently noticed that when the wind blew from the direction of swamps in the vicinity, bringing numbers of mosquitoes, there would be an increase in the number of men, both native and European, down with fever *about a week later*. Had the wind brought the malaria, or dust containing fever germs from the swamps, the increase in number of fever cases might have been expected within two or three days; but as generally a week elapsed, some less direct cause was to be sought, and I always thought the mosquitoes were the culprits.

That mosquitoes do more than inject a specific toxin may be inferred from a fact I have noticed—that people who have been living in the interior of this country and have become inured to the bites of the insects from the swamps, on coming to this town, where sewerage and dirt of all descriptions abound, are painfully conscious of the attacks of mosquitoes here, and *vice versâ*.

Those who have suffered much from fever are generally immune from the usual pain of mosquito bites, and I have heard natives say that they have suffered so much from fever that even the mosquitoes will not bite them.

During the summer months, in certain localities in the interior, labourers are exposed to the bites and stings of tarantulas and scorpions. I have frequently seen men stung several times in the same season, and found that *invariably* they suffered less from each successive sting or bite. J. BLISS.

Smyrna, March 12.

The Stereoscopic Studies of Clouds.

SINCE 1894, I have been making stereoscopic studies of clouds with wide separation of the cameras.

Beyond the direct interest of the pictures, the method has a practical value.

(1) In the measure of the distance of clouds by photogrammeters, it is usual to mark by a pin-prick the corresponding points of the two prints. Through the vagueness of cloud outlines it is easy to err in doing this, but any error thus made is easily detected by the stereoscope.

I have recently learnt that this method has been already suggested by Mr. M. J. Amsler-Laffon, of Schaffhausen, but I do not know whether it has been previously put to a practical test.

(2) My photographs were taken by visible signal without electric connection, some of them with a base of fully five hundred yards, and the clear stereoscopic definition seems to show that in ordinary cases the expensive electric connection of the cameras may be dispensed with, without affecting the value of the plates for purposes of measurement.

19 The Boltons, S.W. JOHN TENNANT.

FAMOUS SCIENTIFIC WORKSHOPS.

I.—LORD KELVIN'S LABORATORY IN THE UNIVERSITY OF GLASGOW.

AS Lord Kelvin stated nearly twelve years ago, in an address at the opening of the Physical and Chemical Laboratories at the University College of North Wales, the establishment of scientific laboratories at universities and colleges for the experimental training of students is a comparatively recent idea. Private laboratories, no doubt, existed at a very early period. The old alchemists had places, sometimes secret retreats, meanly appointed, like the den of Wayland Smith, sometimes, when the purse and protection of a powerful patron were at their command, more luxurious quarters, in which they carried on their search for the elixir of life, and the key to the transmutation of metals.

> Der in Gesellschaft von Adepten,
> Sich in die schwarze Küche schloss,
> Und, nach unendlichen Recepten,
> Das Widrige zusammengoss.

When what was spurious and unscientific in the old alchemy had gradually sublimed away, when chemistry had grown up in its place, and the experimental study of natural philosophy had begun, the only laboratories (anatomical schools excepted), as a rule, were those in the houses of investigators, and to these admission was given by the masters only to their favourite disciples. There the work done was entirely that of research: such a thing as a course of laboratory exercises, carried on with a view to the passing of an examinational test of experimental knowledge and dexterity, was undreamed of. What a change has taken place! Now, no scheme of instruction in physics, chemistry, or biology is deemed complete which does not include an extensive course of practical work to be performed by the ordinary students; and excellent and well-appointed laboratories are provided at every institution which aims at giving university instruction in scientific subjects. This is all as it should be, were it not that the examinational test is in too many cases made a great deal too much of.

The Scottish Universities have often been criticised adversely, most frequently by men who knew little about

them or the work they do, but on several memorable occasions they have led the way in scientific progress. To a resident graduate of the University of Cambridge the world owes the Newtonian Philosophy, but it was James Gregory, in the University of St. Andrews, who first taught the Newtonian doctrines in a University course; and Lord Kelvin was, we believe, the first teacher of Natural Philosophy who opened a physical laboratory to his students. The beginning was a memorable one. Soon after his appointment fifty years ago to the Glasgow Chair, Lord Kelvin was beginning his great series of researches on the Electrodynamic Qualities of Matter, and invited his students to aid him. Others hearing of the new work going on volunteered for service, and new branches of research were quickly opened out. Then began that famous experimental work which has been carried on at Glasgow through half a century, and still so actively continues.

The physical laboratory for many years was a disused wine-cellar in the old University buildings. To this was added, in course of time, the discarded Blackstone examination room, and in this modest suite of rooms the experimental work of the department was done, until the University removed twenty-six years ago to its palatial buildings at Gilmorehill.

For the most part the work done in this laboratory was of the nature of research. A good man was set to make some of the easier observations in an investigation which was in progress, and, beginning thus, he in a short time obtained very considerable skill in experimental processes by carrying out the determinations of the various physical constants which were required for the final result. For the best men this plan answered remarkably well. Their interest was excited, was kept alive by their constant intercourse with the guiding spirit of the place, and their zeal was such that, as the writer can testify, the laboratory corps, as it used to be called, has been known to divide itself into two squads—one which worked during the day, the other during the night, for weeks together, so that the work never paused.

The University of Glasgow is built somewhat after the fashion of colleges in Oxford and Cambridge, in the form of a double quadrangle, and in a style of Gothic architecture, with crow-step gables and turrets, rather common in baronial residences in Scotland.

Although the amount of space devoted to the Department of Natural Philosophy in the University is considerable, the physical laboratory, it must be confessed, suffers from the general plan adopted for the buildings. Of the convenience of the quadrangular arrangement for a college, consisting in the main of suites of rooms for students and fellows, with dining-rooms, class-rooms, &c., there can be no question; but for a *university*, in which provision must be made for great experimental departments, such as physics, chemistry, physiology, zoology, and anatomy, it is far from being well adapted. Such departments are best provided for by detached buildings, or "Institute," as they are called in Germany, if possible within the University grounds.

The adjoining figure gives a view of a part of the general working laboratory. In the foreground is a writing-table, on which stands a magnetostatic voltmeter. At that table Lord Kelvin generally sits when he is in the laboratory, and occupies himself with the consideration of results which are being obtained by the men at work in the laboratory, or with the dictation of his correspondence to his secretary.

A little to the right is a stone erection built on an independent foundation. This contains a chamber in which apparatus requiring a steady support can be suspended; and it was here that the pendulum was hung by which Messrs. George and Horace Darwin made their first attempt to determine directly the attraction of the moon on a body at the earth's surface.

Behind the writing-table is another table with vertical beams at its corners, which give it somewhat of the appearance of a "four-poster" bedstead. To these vertical beams cross-bars are attached for the support of pieces of apparatus in the manner shown in the illustration.

[*From a photograph by T. and R. Annan and Sons, Glasgow.*

Fig. 1. View of part of the General Laboratory.

In the background are two stone pillars supporting a partition wall of the rooms above, and to these were led wires from a large battery of tray Daniell cells which, before the advent of really practical dynamos, stood in the right-hand corner of the laboratory under the staircase, and supplied the current required for the various kinds of experimental work in progress. On the left of the pillars is seen part of another four-poster, and the door of a private room, partitioned off from the main laboratory, in which special experiments, or reductions of results can be carried on without interruption.

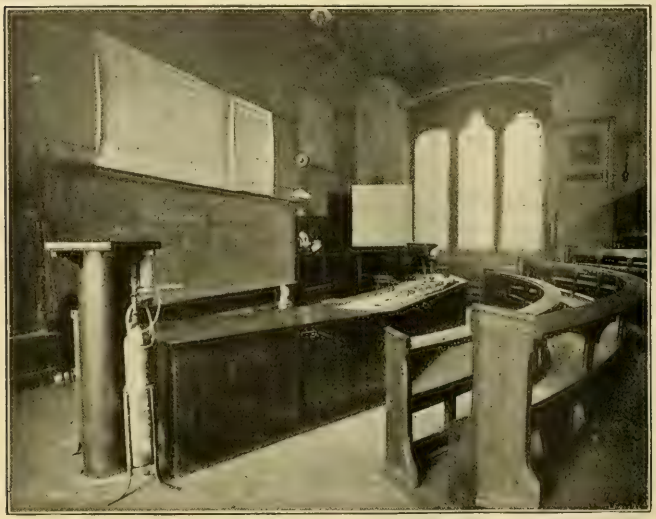
Passing up the stairway, seen at the back in the illustration, we arrive on the upper floor in a small room formed under the seats of the Lecture Theatre. Thence we can pass directly into the Lecture Theatre, or into the Apparatus Room, which is directly behind it.

The adjoining figure gives a view of the interior of the Lecture Theatre as seen from its large oriel window in the front of the building. It is a lofty apartment lighted mainly by two large windows, one the oriel just referred to, the other, seen in the picture, looking into the west quadrangle. On the sill of the latter window, which is passed each day by every student entering or leaving the room, are usually arranged a series of semi-secular experiments, in illustration of those lectures on the "Properties of Matter," which have always formed a most interesting and suggestive part of Lord Kelvin's course, and which, to every one who has heard them, have intensified the regret, felt by so many, that the second volume of Thomson and Tait's "Natural Philosophy," in which this subject was to be specially treated, is not to appear.

In one of these experiments a slab of pitch, or of shoemakers' wax in water in a glass jar, is made to confine a number of common corks below it, while in the water above the jar are placed a few lead bullets. After a month or two some of the corks are found in the water above the pitch, while the lead bullets have sunk down through the pitch to the bottom of the jar. Other corks are on their way through, and, being imbedded in the pitch, are lost to view; and of the paths followed by the corks and bullets, which have made the passage, no trace remains. All the time the pitch or wax is so brittle as to fly to pieces if thrown down on a table, or violently struck with a hammer.

To the small continuously applied forces due to the corks and bullets the pitch has behaved like a fluid; indeed, its properties have been precisely those of a highly viscous liquid. It has offered resistance to change of shape, but the resisting force has depended on the rate of progress of the change, not, as elastic resistance would, on the amount of change already accomplished. On the other hand, a piece of the same pitch melted into the form of a bell, and struck with a hammer in the ordinary way, would give out a musical note, showing that for rapidly alternating changes of shape the forces excited in the pitch are proportional to the strains produced; which indicates that the material under the latter conditions possesses the properties of a solid. Thus one and the same substance may, according to the circumstances in which it is placed, behave either as a viscous liquid or as an elastic solid.

This result is important as bearing upon the difficulty as to how the luminiferous ether, under any conceivable estimate of its density, can possess so high a degree of rigidity as to transmit the waves of transverse oscillation, which, according to the elastic solid theory of the ether, we have in light, with a velocity of 3×10^{10} centimetres per second; while the planets and the components of double or multiple stars move freely through it. The difficulty (if it is a real difficulty, and is not to be got rid of in a new view of the propagation of light based on electromagnetic theory) is not explained by this experiment; but it is reduced by it to an affair of properties of matter, by being shown to have a parallel in a phenomenon of which we have undoubted experience.



From "Good Words." [*From a photograph by T. and R. Annan and Sons, Glasgow.*

FIG. 2.—Lecture Theatre, from front window.

Another piece of apparatus in the window is a model glacier in which a slope of wood takes the place of the sloping bed on the mountain-side, and shoemakers' wax that of ice. [See Dr. Bottomley's description in NATURE for December 18, 1879 (vol. xxi. p. 159).]

In the window also are generally displayed tubes illustrating the diffusion of liquids into one another, and the osmotic passage of a sugar solution through a diaphragm.

On the other side of the room is a large oriel window, which is partly visible in the view of the class-room table and lecture apparatus given in Fig. 3. Set up in this oriel window are two tall tubes running nearly the whole height of the room, and protected by wooden cases fitted with glass doors. One of these tubes illustrates the diffusion of sulphate of copper solution upwards into water, and the water itself in the opposite direction. The other tube shows the same thing for water and alcohol. These tubes were set up nearly a quarter of a century ago, soon after the new building was taken possession of by the University; and the original surfaces of separation, with the dates, are marked upon them. This is, perhaps, the longest experiment on diffusion that has ever been carried on; but of course it is capable of infinite duration, as an infinite time would have to elapse before the liquids in the tubes were completely mixed by this process. In his lectures Lord Kelvin is fond of accomplishing the work of an infinite time in diffusion, by reversing two or three times a closed tube in which the liquids have been originally separated by their different specific gravities.

The progress of diffusion in the secular experiments is shown by the motion of specific gravity beads (small

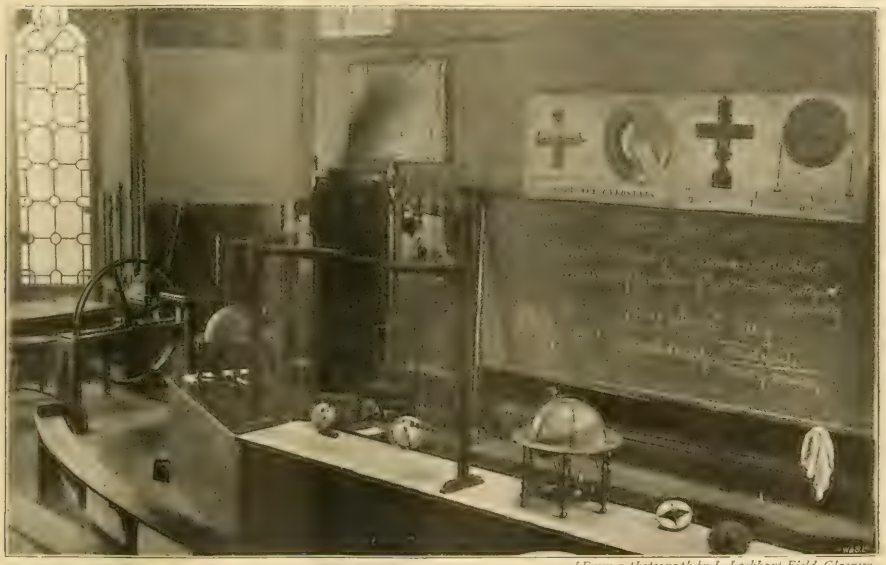
beads of glass of known mean specific gravity), which float in the liquid, and mark by their change of position the advance within the liquid of a stratum of given density. Thus the state of the liquids can be seen at a glance without either disturbing the apparatus, or setting up more or less troublesome observing instruments.

The picture shows the lecture-table with apparatus for illustrating gyrostatic action and precessional motion. On the table and to the right are ordinary gyrostats, towards the left are two hollow spheroidal gyrostats which can be filled with water, and between stands a model, well known to all Glasgow students, for illustrating the precessional motion of the earth, which arises from its gyrostatic action. One of the hollow spheroids is oblate, the other is prolate, with the same deviation from sphericity in each case. When they are filled with water and rotated, the oblate spheroid behaves like an ordinary solid gyrostat; the motion of the other is unstable, and the spin disappears immediately. On the wall are diagrams showing the construction of a gyrostat and its rotational stability under various modes of support which render it essentially unstable when there is no rotation.

Above the lecture-table is a large opening extending to the roof, so that it is possible to suspend from the roof-beams pendulums, ropes, gyrostats, and many other things of great importance for physical illustration.

The apparatus-room is a large apartment, like the other rooms of the laboratory, from eighteen to twenty feet in height. It contains two large cases of instruments occupying a large part of the floor-space, and two smaller wall-cases at the ends of the room. Here are stored the instruments used for class illustrations and research; but in the cases also are many pieces of apparatus, quaint and old-fashioned in form and ornamentation, made to a great extent from fine old mahogany. Besides these "urväter Hausrath" the cases contain several instruments of more modern design, which are far more historically interesting. One of these is the first reflecting galvanometer used by Lord Kelvin as a receiving instrument for signals through a submarine cable, the identical galvanometer, in fact, with which signals were received on board ship in the famous cable expedition of 1857, 1858; another is one of the pieces of apparatus with which Joule determined the dynamical equivalent of heat; and another is a replica of Dr. Andrews' apparatus for the investigation of the critical states of gases.

In another room upstairs there used to be a complete museum of electrometers and other electrical instruments. There were to be found old attracted disc-, heterostatic, and idiostatic-electrometers, and a series of instruments illustrating the development of the quadrant form of electrometer, from the first rude model to the marvellously complete and delicate contrivance for measuring differences of electric potential, which is not one of the least of the benefits Lord Kelvin has conferred on electrical science.



[From a photograph by J. Lockhart Field, Glasgow.

Fig. 3.—Lecture Table, with gyrostats, precessional globe, &c., and diagrams illustrating gyrostatic action.

Beyond the lecture-room, on the side remote from the apparatus-room, is the private room of the Professor of Natural Philosophy. There Lord Kelvin, in the early years of the new University buildings, used to work a good deal. Now the private room is occupied for the most part by his nephew, Dr. J. T. Bottomley, who has had the adjoining room fitted with benches, mercury air-pumps, and other apparatus suitable for investigation of the properties of high vacua.

On the floor above the apparatus-room and lecture-room are further cases for apparatus, and a battery-room the floor of which is caulked to prevent liquid from passing through into the rooms beneath.

The Physical Department and Lord Kelvin's house at the University are lighted with electricity. Current is generated for this purpose by a dynamo driven by a

gas-engine in a small room on the ground-floor adjoining the general physical laboratory. The dynamo is kept continually running, and feeds a large secondary battery in another small room above the engine-room. This battery is used to supply current for special laboratory purposes, and also to feed and regulate the incandescent lamps throughout the department.

Perhaps the first telephone line to be established in this country was that erected between the University and the instrument factory of Mr. James White, who used to be well known as Lord Kelvin's instrument-maker. This line existed alone for some time, and formed the nucleus from which sprang the Glasgow Telephone Exchange, one of the first to be established in Britain.

Before leaving the laboratory proper we must not omit to mention the secular experiments on the effect of long-continued pulling stress on the length of wires of different materials, which are being carried out under the superintendence of Dr. J. T. Bottomley in one of the lofty rooms of the University tower. There, within a case of iron extending from a short distance above the floor of one room to the bottom of the one beneath it, a distance of about sixty feet, are hung wires of gold, platinum, and palladium, two for each metal, one of the two in each case being loaded with three-fourths of the breaking weight, the other with about one-tenth of the breaking weight. The lengths of these wires are observed from time to time by Dr. Bottomley by means of a cathetometer specially constructed for the purpose (see B.A. Rep., 1879, 1886).

In the same room there used to exist, and probably exists still, a mercury pressure-gauge, consisting of a long iron tube running for about 100 feet down a well which passed from the lofty room in which the wires are suspended to another below it in the tower.

In speaking of Lord Kelvin's laboratory we ought not to confine ourselves to the University laboratory, or even to Glasgow. Lord Kelvin's house, for example, is part of his laboratory; in fact, in a very true sense his laboratory or workshop includes wherever he happens to be. In train and steamer, at home or abroad, he is ever at work; and, no matter where he may be, he is in constant communication by post and telegraph with the corps of workers at Glasgow, is in daily receipt of the results of their work, and occupied with the deduction of consequences, and the consideration of how the researches in progress may be developed and extended.

The adjoining figure is a view of Lord Kelvin's study in his house at the University. The writing-table at the window is that generally used by Lord Kelvin; that in the middle of the room is the table of his secretary. In this room he spends several hours of each day, when he is at home, carrying on his literary work with his secretary, contriving models to illustrate the arrangement of the molecules in a crystal, molecular tactics, or mechanism for imitating the functions of the luminiferous ether, or occupied with one of his numerous inventions.

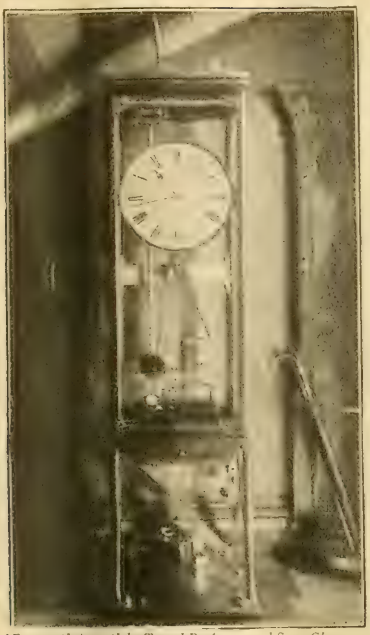
From "Good Words." [*From a photograph by T. and R. Annan and Sons, Glasgow.*

FIG. 4.—Interior of Study in Lord Kelvin's House at the University of Glasgow.

The practical applications of physical science which Lord Kelvin has made are very varied, and they still occupy a considerable amount of his time and attention. Just outside his study, in the hall of his Glasgow house, stands a very remarkable clock which is designed to run at an almost strictly uniform rate (instead of discontinuously, like ordinary clocks and watches), and to show Greenwich mean time to a higher degree of approximation than is possible with a clock possessing any of the ordinary escapements. A full account of this clock is to be found in NATURE for January 11, 1879 (vol. xv. p. 227).

The instrument-making establishment formerly presided over by James White, and now carried on by a firm which has succeeded him, is a large factory situated in Cambridge Street, Glasgow, and in many respects may be considered a branch of Lord Kelvin's laboratory. A portion of it is shown on the next page (Fig. 6). The workshops consist of several floors, which are set apart for different departments of the work carried on. An 80-H.P. engine supplies power for the machinery, which comprehends many instruments and tools, such as lathes, &c., of precision. A large and fully-equipped standardising laboratory is provided on the ground-floor for the graduation of the standard electrical instruments which Lord Kelvin has recently placed in the hands of practical electricians.

Here his various navigational and electrical instruments are made, tested, and sent out for use; and here, when at home, he spends a part of almost every day. His usual programme is, after giving instructions regarding the correspondence of the morning to his secretary, and lecturing to his class from 9 to 10 o'clock, if it is one of his days to do so, to walk or drive into town to White's, there often to remain until time to return to the University for a midday lecture or for luncheon. In these visits to White's many scientific problems have been solved, and many others have been suggested, the solution of which, if unattainable, had to be avoided by



[*From a photograph by T. and R. Annan and Sons, Glasgow. From "Good Words."*]

FIG. 5.—Astronomical Clock in the Hall of Lord Kelvin's House.

material. This in its turn, owing to the invention of telephony, has had to be modified by the introduction of quantities which, neglected before, become in rapid periodic signalling of primary importance. Thus we have the complete theory of the propagation of electric waves along wires, with which we have been made familiar by the researches of Lord Kelvin himself, Heaviside, J. J. Thomson, and Hertz.

Another important part of Lord Kelvin's real laboratory used to be his yacht. For many years his commodious schooner, the *Lalla Rookh*, was put in commission early in April; and from then till the end of October, Lord Kelvin sailed the seas. Sometimes he went as far as Madeira, or up the Mediterranean, but generally he cruised between the Clyde or the Hebrides and the Solent. Wherever he was, he was busy with scientific research, and the mathematical discussion of some abstruse problem in fluid motion, carried on with notebook and pencil, alternated with a trial of some new form of sounding machine, or an observation of waves or ripples. Lord Kelvin is a thoroughly skilled and scientific navigator; in fact he is one of the most distinguished authorities, not only on matters of physical science, but also on questions of naval architecture and practical navigation.

In all the work of the Physical Laboratory the aim has ever been to render the student self-dependent and resourceful. The writer well remembers being told, not long after he entered the laboratory, that he ought to have taken to pieces a quadrant electrometer to find out what prevented it from acting properly, when all else had failed to disclose the fault in the instrument. And many others have had similar experience. It is very doubtful, indeed, if too much is not done for students in many laboratories, in the way of arranging for their individual pieces of work, and furnishing them with ready set-up and unexceptionable instruments.

But beyond everything in the laboratory at Glasgow has ever been Lord Kelvin's presence and example, and

adopting some other means of obtaining the desired result. These constant relations of practice to theory and theory to practice, which Lord Kelvin, in consequence of his great inventive activity, has had always to keep in view, have been fraught with important consequences to science.

It would be difficult to say how many of Lord Kelvin's contributions to the advancement of pure science have resulted from his keen interest in applications of science, and his knowledge of the resources and uses of mechanism; but it is certain that many of them may be credited to this account. It was the practical question of how to signal at a rate commercially successful through a submarine cable that led him to the discussion of the diffusion of electricity through a long copper conductor, separated from an external conductor by a cylindrical sheathing of insulating

From "Good Words."] [*From a photograph by T. and R. Annan and Sons, Glasgow.*

FIG. 6.—A part of James White's Instrument Factory.

the charm of his personal influence. Throughout his long tenure of the chair of Natural Philosophy, he has carried lightly like a flower the weight of honour which the scientific world has united to render to him. He has remained ever the same kind friend of his students, and his interest in them, old and young, and in every scientific worker, has found many quietly sympathetic modes of expression. The enthusiastic testimony to his pre-eminence as a scientific man, and to his admirable personal qualities, which was borne by the whole world at the magnificent celebration last June, will not soon be forgotten by those who had the privilege of taking part in that great ceremonial: it was an emphatic tribute to the greatness of the part which the Physical Laboratory at Glasgow has played in science during the last fifty years. A. GRAY.

JAMES JOSEPH SYLVESTER.

HE is dead, and it becomes a sad duty to give a brief account of his long life and great work.

Born in London September 3, 1814, he was the youngest but one of seven children of Abraham Joseph Sylvester. He was the last survivor. Three sisters lived for many years at Norwood, and of his three brothers two, Frederick and Joseph, lived for the most part in America, whilst George resided at Worcester.

He obtained his early education at private schools in London; thence he went to the Liverpool Institution, and in 1837 graduated at St. John's College, Cambridge, as Second Wrangler. The first five names in the Mathematical Tripos of the year are Griffin, Sylvester, Brumell, Green, Gregory. It is astonishing to think that Green, of immortal memory, has been dead for nearly fifty years! Sylvester was keenly disappointed at his failure to be senior of the year. He was always of an excitable disposition, and it is currently reported that, on hearing the result of the examination, he was much agitated. Being of the Jewish persuasion, he was unable to take his degree at Cambridge, but later he obtained a degree at the University of Dublin. On leaving Cambridge he at once commenced the long series of mathematical papers, which he was to contribute to scientific periodicals all over the world, by the publication, in vol. xi. of the *Philosophical Magagine*, of an analytical development of Fresnel's optical theory of crystals.

This was followed by some articles upon subjects of applied mathematics, and it was not until 1839 that he brought his intellect to bear upon the analysis of continuous and of discontinuous quantity, departments of pure mathematics which well-nigh monopolised his attention for the remainder of his life. He was appointed Professor of Natural Philosophy at University College, London, and later on held the post of Professor of Mathematics in the University of Virginia. He returned to England in the year 1845, and the first period of his scientific career may be said to have closed. He had published some thirty papers, and was already well known in both hemispheres as an original and imaginative man of science. The subjects dealt with comprise "Dialytic Method of Algebraical Elimination," "Sturm's Functions," "Criteria for Determining the Roots of Numerical Equations," "The Calculus of Forms" (afterwards known as the "Theory of Invariants"), "The Equation in Integers $Ax^3 + By^3 + Cz^3 = Dxyz$." The latter problem was a favourite subject of thought throughout his life, and the first problem in the theory of numbers that he attacked. The theory of invariants sprang into existence under the strong hand of Cayley, but that it emerged finally a complete work of art, for the admiration of future generations of mathematicians, was largely owing to the flashes of inspiration with which Sylvester's intellect illuminated it. The nomenclature of the theory is almost entirely due to him. The words "invariant," "covariant," "Hessian," "discriminant," "contravariant," "combinants," "commutant," "concomitant," are a few of those introduced by him at this time, which have been part of the stock-in-trade of mathematicians ever since.

A beautiful theory of the rotation of a rigid body about a fixed point, after Poinsot, should be mentioned. It is one of the few papers that he wrote on dynamics.

For ten years after his return from Virginia he was occupied with a firm of actuaries. He founded the Law Reversionary Interest Society, and also accomplished a considerable amount of mathematical research. In 1853 appeared his first important memoir in the *Philosophical Transactions* of the Royal Society, bearing the title, "On a theory of the syzygetic relations of the rational integral functions, comprising an application to the theory of Sturm's functions and that of the greatest algebraical common measure." This is a masterly exposition, covering 170 quarto pages.

In 1855 he was appointed Professor of Mathematics at the Royal Military Academy, Woolwich. This was a great relief, as the work of an actuary was manifestly unsuitable, and had indeed been most distasteful to him. He held this professorship for fifteen years. It was a time of great activity. Year by year his fame increased, and recognition by foreign academies was liberally bestowed. In addition to continual work at the theory of invariants, he laboured at some of the most difficult questions in the theory of numbers.

Cayley had reduced the problem of invariant enumeration to that of the partition of numbers. Sylvester may be said to have revolutionised this part of mathematics by giving a complete analytical solution of the problem, which was in effect to enumerate the solutions in positive integers of the indeterminate equation—

$$ax + by + cz \ldots + ld = m$$

Thereafter he attacked the similar problem connected with two such simultaneous equations (known to Euler as the Problem of the Virgins), and was partially and considerably successful. In June 1859, he delivered a series of seven lectures on compound partition in general at King's College, London. The outlines of these lectures, printed at the time for distribution amongst his audience, are now being published for the first time by the London Mathematical Society. He was assisted in the preparation of these lectures by Captain (now Sir Andrew) Noble, with whom from that time forth he was in sympathetic friendship.

The year 1864 may be regarded as the time of his greatest intellectual achievement, which caused him to be considered as one of the foremost of living mathematicians. On April 7, 1864, he read a paper before the Royal Society of London, bearing the title "Algebraical Researches, containing a disquisition on Newton's rule for the discovery of imaginary roots, and an allied rule applicable to a particular class of equations, together with a complete invariantive determination of the character of the roots of the general equation of the fifth degree, &c." In the "Arithmetica Universalis," Newton gave a rule for discovering an inferior limit to the number of imaginary roots in an equation of any degree, but without demonstration. Neither did he give any indication of the mental process by which he was led to conjecture the truth of the rule, nor did he set forth the evidence upon which it rests. For years the question of proving or disproving the rule had been a crux of the science. Euler, Waring, Maclaurin and Campbell were amongst those who sought in vain to unravel the mystery. The only step that had been gained was to show that if *any* negative terms occur in the quadratic elements involved in the statement, there must be *some* imaginary roots. This, however, was not a great step,

as a slight consideration renders it apparent. Sylvester, in the paper quoted, established the validity of the rule for algebraical equations as far as the fifth degree inclusive. The method employed was that of "infinitesimal substitution," which he himself initiated, and had previously employed in an essay, "On the Theory of Forms," in the *Cambridge and Dublin Mathematical Journal*. It proceeded upon the principle that every finite linear substitution may be regarded as the result of an indefinite number of simple and separate infinitesimal variations impressed upon the variables. He also discussed the probability of the specific superior limit to the number of real roots in a superlinear equation equalling any assigned integer. This valuable memoir contained only a small instalment of the desired result. It was not till the following year—1865—that he fully established and generalised the conjectured theorem of Newton. On June 19, he communicated the substance of his discoveries to the Mathematical Society of London, Prof. de Morgan being in the chair as its first president; and on the following June 28 he gave a public lecture in King's College, London, taking as his title, "On an elementary proof and generalisation of Sir Isaac Newton's hitherto undemonstrated rule for the discovery of imaginary roots." Sylvester's fame with posterity will, perhaps, be principally associated with this great intellectual triumph. It may be observed that, subsequent to the demonstration, Dr. J. R. Young claimed to have proved Newton's rule twenty years before. Sylvester contested this assertion in a characteristic manner, and mathematicians are, I think, in agreement that he showed it to be without basis. He always wrote well and with considerable power of expression; but, perhaps, he was strongest when attempting to demolish any one who questioned or denied his claim to priority in a particular mathematical discovery. In the case in point he wrote: "It is such stuff as dreams are made of, and culminating as it does in a palpable *petitio principii* does not need a detailed refutation at the hands of the author of this lecture. It is not by such vague rhetorical processes, but by quite a different kind of mental toil, that the truths of science are won, or a way opened to the inner recesses of the reason."

When the British Association for the Advancement of Science met at Exeter, in 1869, Sylvester was the President of the Mathematical and Physical Section. Huxley had recently written in *Macmillan's Magazine*: "Mathematical training is almost purely deductive. The mathematician starts with a few simple propositions the proof of which is so obvious that they are called self-evident, and the rest of his work consists of subtle deductions from them"; and again, in the *Fortnightly Review*: "Mathematics is that study which knows nothing of observation, nothing of experiment, nothing of induction, nothing of causation." It may be safely said that any man engaged constantly in mathematical research would find no difficulty in refuting these statements to the satisfaction of any representative body of scientific men. Sylvester devoted a considerable portion of his address to the Section to contesting Huxley's statements, and put in a powerful and eloquent plea for mathematics as being a science of observation and experiment, and as affording a boundless scope for the exercise of the highest efforts of imagination and invention. Huxley, I believe, made no reply; and I think there can be no doubt that, like many other remarkable men in other branches of science, he had no conception of the real nature of the life-work of mathematicians of the high order to which Sylvester belonged. Amongst other matters in his address, he remarks upon the extraordinary longevity of the masters of mathematics. Amongst these long-lived ones he himself now takes an honourable place.

He left Woolwich (for years he occasionally wrote from his house on the Common, over the *nom de plume* "Lani Vicencis") in 1870, and for some years was without a professorship. During this time he was much interested in the problems of link-motion and conversion of motion generally. He wrote several valuable papers and invented the skew pantigraph. The title of one of his papers of this period is characteristic—"Mode of construction and properties of a new sort of lady's fan and on the expression of the curves generated by any given system whatever of link work under the form of an irreducible determinant."

He gave a Friday evening lecture at the Royal Institution, entitled "On Recent Discoveries in Mechanical Conversion of Motion."

His acceptance, in the year 1875, of an invitation to become the first Professor of Mathematics in the new Johns Hopkins University at Baltimore, in Maryland, may be regarded as concluding the second period of his career. He could hardly expect to further increase his reputation, which was extraordinarily high, and most of the honours that can fall to the lot of a scientific man had long been in his possession.

In Baltimore he soon founded the *American Journal of Mathematics*, and was surrounded by a knot of enthusiastic students, whose researches he was able to influence, and in some cases to entirely direct. His final investigations in the theory of algebraic invariants, various questions in diophantine analysis, the constructive theory of partitions, the theory of universal algebra, and the commencement of his researches on differential invariants, were principally the outcome of his residence in Baltimore. He was assisted, followed up, and frequently also inspired by his students in an ideal manner. Perhaps the most permanent impress he left on the path of American research was in the subject of universal algebra, the vigorous offspring of Cayley's memoir, of 1858, on matrices. He established the nomenclature of the subject and surveyed the unknown country. He showed the connection between linear transformation and quaternions, and further arrived easily at a generalisation of quaternions. Since then Taber, Metzler, and others in the New World, have made valuable additions to the theory.

In 1883 he was elected to succeed Henry J. Stephen Smith in the chair of the Savilian Professorship of Geometry at Oxford. His inaugural lecture was on the subject of differential invariants, termed by him reciprocants. This work was extensive and important, and its elaboration, with the able assistance of James Hammond, was the last valuable contribution he made to mathematics. With increasing age infirmities came upon him. He suffered from partial loss of sight and memory, and in 1892 he obtained permanent leave from his duties, and the University appointed a deputy professor.

Henceforth he lived for the most part in London, and was a familiar figure in the Athenæum Club, but he was never in good health. At intervals he would go down to Tunbridge Wells and live at the Spa Hotel, but he did no mathematical work, and his frame of mind was not happy. Early in 1896, his condition caused alarm to his friends. In August he quite suddenly became again interested in mathematical subjects, and this appeared to make him calmer and happier. On February 26, whilst working at the theory of numbers, he had a paralytic stroke and never spoke again. He died peacefully at 3.30 a.m. on Monday, March 15, 1897, at 5 Hertford Street, Mayfair.

His work was not so voluminous as that of many of his great contemporaries. It may amount to about 1250 octavo pages and about 1550 quarto pages. Its quality, however, is of a very high order, as he always preferred to labour at difficult questions; problems which for centuries have been a challenge to the human intellect

had an especial attraction for him. His last thoughts were concerning the distribution of the prime numbers; the excellent paper in which he contracted Tchebycheff's limits was a source of great satisfaction to him, and shortly before he died he was hopeful of being able to prove the Goldbach-Euler conjecture that every even number can be partitioned into two primes; but in this he was not successful, although he was able to narrow the issue, and to give a more precise statement of the supposed theorem. At one time he was interested in the construction of tessellated pavements; one anallagmatic design was, through the influence of his friend Colonel Yelverton, put down in the hall of the Junior United Service Club in Charles Street, Haymarket. Some years ago it was unfortunately removed whilst the hall was undergoing repair.

His writings are flowery and eloquent. He was able to make the dullest subject bright, fresh, and interesting. His enthusiasm is evident in every line. He would get quite close up to his subject, so that everything else looked small in comparison, and for the time would think and make others think that the world contained no finer matter for contemplation. His handwriting was bad, and a trouble to his printers. His papers were finished with difficulty. No sooner was the manuscript in the editor's hands than alterations, corrections, ameliorations and generalisations would suggest themselves to his mind, and every post would carry further directions to the editors and printers. His usual custom was to send early notice of his discoveries to the Academy of Sciences in Paris. Subordinate theorems he would despatch at once to the *Educational Times*. He frequently also made announcements in the columns of NATURE. He gave so many names to mathematics that he used playfully to speak of himself as the Mathematical Adam. It has been remarked by Prof. Forsyth that he drew almost entirely upon Latin for new names, whilst Cayley as invariably drew upon Greek. In 1870 he published "The Laws of Verse," dedicating it to Matthew Arnold. The composition of sonnets, both in English and Latin, was a relaxation that he much enjoyed; these have been, and no doubt will be, criticised in other places.

He was fond of billiards, whist and chess. He liked occasionally going into the society of ladies, but was never married.

He appears in the series of portraits of Scientific Worthies for the year 1889, to the accompaniment of a sympathetic notice from the pen of Cayley. His portrait in oils, by Elmslie, was exhibited in the Royal Academy a few years ago, and now hangs in the hall of St. John's College, Cambridge. His physiognomy was striking, never failing to impress deeply at a first meeting. Latterly his appearance was venerable and patriarchal.

In this short notice justice cannot be done to his character. His temper was somewhat quick on occasions, but he never cherished angry feelings beyond a very short time; he was anxious to forget and forgive. Only those who understood him were aware that anger or displeasure was with him a transient phenomenon, and that charitableness of feeling and kindness of heart were characteristics deeply engraved upon his nature. To younger men he was sympathetic and generous.

The revival of the mathematical reputation of England, dating from the Queen's accession to the throne, is to a large degree due to his genius; and those who were present on March 19, at the simple, yet impressive ceremony at the Jewish cemetery at Dalston, must have realised that one of the giants of the Victorian era had been laid to rest. The Royal Society and the London Mathematical Society were represented at the funeral by Prof. Michael Foster, Sec.R.S., Major MacMahon, R.A., F.R.S., Prof. Forsyth, F.R.S., Prof. Elliott, F.R.S., Dr. Hobson, F.R.S., Prof. Greenhill, F.R.S., Mr. A. B. Kempe, F.R.S., and Mr. A. H. Love, F.R.S. There were also present Prof. Turner and the Sub-Warden of New College, Oxford.

P. A. MACMAHON.

NOTES

A MEETING of Presidents of various scientific societies in London was recently convened by the President and Officers of the Royal Society, to consider whether any, and if so what, steps should be taken to commemorate the sixtieth year of Her Majesty's reign. It was unanimously resolved—"That a fund to be called the Victoria Research Fund be established, to be administered by representatives of the various scientific societies, for the encouragement of research in all branches of science." The President of the Royal Society has communicated this resolution to the scientific societies, with a letter asking whether support would be given to it.

AT the recent anniversary meeting of the Royal Irish Academy, Prof. Albert von Kölliker and M. A. Michel Lévy were elected honorary members in the Section of Science.

THE subject of the Croonian Lecture to be delivered at the Royal Society on Thursday next, by Prof. C. S. Sherrington, is "The Mammalian Spinal Cord as an Organ of Reflex Action."

THREE sculptors—Lessing, Hertert, and Janensch—have been selected from the list of those who made application to execute the statue of Helmholtz for the Helmholtz Memorial Committee. Which of the three will be chosen to carry out the work is not yet known. The monument will stand between the statues of the two Humboldts, in the front grounds of the University of Berlin.

WE much regret to announce the death of M. Antoine T. d'Abbadie, formerly president of the Paris Academy of Sciences. In 1893 M. d'Abbadie bequeathed to the Academy, subject to a life-interest to his wife, the Abbadia estate in the Pyrenees, having an annual revenue of twenty thousand francs, and shares in the Bank of France representing an annual income of fifteen thousand francs. He published several important works on geographical exploration and geodesy, and was sent by the Academy to St. Domingo in 1882 to observe the eclipse of the sun.

THE following are the names of the members of the British Association who have been nominated by the Council as presidents of the different Sections at the forthcoming meeting at Toronto:—(A) Mathematical and Physical Science, Prof. A. R. Forsyth, F.R.S.; (B) Chemistry, Prof. W. Ramsay, F.R.S.; (C) Geology, Dr. G. M. Dawson, C.M.G., F.R.S.; (D) Zoology, Prof. L. C. Miall, F.R.S.; (E) Geography, Mr. J. Scott Keltie; (F) Economic Science and Statistics, Prof. E. C. K. Gonner; (G) Mechanical Science, Mr. G. F. Deacon; (H) Anthropology, Prof. Sir W. Turner, F.R.S.; (I) Physiology, Prof. M. Foster, Sec.R.S.; (K) Botany, Prof. H. Marshall Ward, F.R.S. The two evening discourses will be delivered by Prof. Roberts-Austen, C.B., F.R.S., and by Prof. John Milne, F.R.S.

MR. MORRIS K. JESUP, president of the American Museum of Natural History, is fitting out an elaborate anthropological expedition to undertake a seven years' tour for the study of prehistoric man in all parts of the world, at a cost estimated as over sixty thousand dollars. It will be the most elaborate and best-equipped expedition ever sent out in the interests of anthropology. Mr. Jesup has already done much for scientific research. Several

years ago he fitted out one of the relief expeditions to bring back Lieut. Peary from the Arctics. He also provided funds for the expedition under Prof. Charles S. Sargent, which collected the forestry exhibit known as the Jesup Collection in the American Museum of Natural History, a very complete exhibit of different kinds of wood in the United States. The expedition now contemplated will be led by Prof. F. W. Putnam, the veteran anthropologist, for a long time curator of the Peabody Anthropological Museum at Harvard University, and secretary of the American Association for the Advancement of Science. He will be assisted by Dr. Franz Boas, who has spent several years among the Indian tribes in the north-west of America, and by a corps of assistants. The plan is to proceed first to the north-west coast of North America, north of British Columbia, following the coast up to Alaska and Bering Strait. Thence the party will cross into Asia, and work down to Siberia, to China, along the Indian Ocean, and into Egypt.

A PUBLIC meeting to promote the National Jenner Memorial will be held in the theatre of the University of London, on Wednesday, March 31, at 4 p.m. The chair will be taken by the Duke of Westminster, K.G., and among those who will address the meeting will be Lord Herschell, Lord Playfair, Lord Lister, and Prof. Michael Foster.

PHYSICISTS who will be in Paris during Easter week should endeavour to visit the exhibition of new physical experiments and apparatus at the rooms of the Société Française de Physique, 44 rue de Rennes. The exhibition will be held on Friday, April 23, and Saturday, April 24. The principal experiments brought before the Society during the past twelve months will be repeated each evening at 8 p.m. ; and the apparatus will be on view during the whole of the Saturday.

WE regret to have to record the deaths of Dr. Kolbe, formerly professor of mathematics at the Technical High School at Vienna ; Dr. Robert Hogg, a distinguished horticulturist, and author of numerous works on the vegetable kingdom and its products ; M. Charles Contejean, a young French physiologist known in the biological world by some important researches ; Mr. Lorenzo N. Johnson, formerly instructor in botany in the University of Michigan ; Prof. John Pierce, formerly professor of chemistry in Brown University, U.S. ; and Mr. John Biddulph Martin, the president of the Royal Statistical Society, and a member of several other scientific societies.

AN instance of the solicitude shown by Government departments in Germany towards University professors is related by the Berlin correspondent of the *British Medical Journal*. It appears that Prof. Kayser, the successor of Hertz as Director of the Physical Institute in the University of Bonn, is invalided, and his symptoms seem to point to influences from insanitary surroundings. In consequence, the Prussian Cultus-Minister ordered a thorough examination into the institute building. Prof. Finkler, of Bonn, and Prof. Proskauer, Assistant at the Berlin Koch Institute, have been entrusted with the work, and will submit proposals for alterations, or even partial rebuilding, to the Medical Department of the Ministry.

THE present year being the sixtieth of Sir George Gabriel Stokes's connection with Cambridge, the wish has been expressed that his bust should be executed by some artist of eminence, and should be preserved in the Hall of Pembroke College, Sir G. G. Stokes having been a member of that college since October 1837. A working Committee has been formed for carrying out the proposal, and Mr. Hamo Thornycroft, R.A., has expressed his willingness to undertake the work of executing the bust. The Committee are desirous, if general support is given to the project, that a replica of the bust should also be executed, and presented to the University, in which Sir G. G. Stokes has held the Lucasian Professorship for nearly fifty years. For this double purpose a sum of not less than four hundred guineas will be required, of which amount about one-third has been given or promised. Donations may be paid to the credit of the "Sir G. G. Stokes Bust Fund" at Messrs. Barclay and Co., Mortlock's Bank, Cambridge, or to either of the Secretaries, Rev. C. H. Prior, and R. A. Neil, at Pembroke College.

THE Institution of Naval Architects have made arrangement to hold an International Congress of Naval Architects and Marine Engineers at the Imperial Institute, in the course of the coming summer. The Prince of Wales has consented to act as Honorary President of the Congress, and will deliver the speech of welcome on the opening day. Invitations to take part in the Congress have been sent to the Ministers of Marine of all the principal maritime powers of the world, to the French Association Technique Maritime, to the American Society of Naval Architects and Marine Engineers. A large and representative Reception Committee is in course of formation, and the Council are receiving every encouragement from H.R.H. the Prince of Wales, from the Government, the City of London, as well as from the shipbuilding and shipowning interests throughout the country. The exact date of the Congress is not yet fixed, but the meetings will probably take place early in July.

THE Comité d'Organisation of the seventh International Geological Congress, to be held at St. Petersburg from August 29 to September 4, have received so many applications from persons who are not geologists, and yet wish to obtain free railway tickets and to participate in other advantages arranged by the Russian Government, that they have issued a special circular stating that the facilities offered are intended only for geologists. Excursion tickets will only be granted to persons who are known by their contributions to geology. Even with this restriction, the meeting promises to be a large one, for more than six hundred geologists have applied for tickets. All geologists who have paid their subscription will obtain a non-transferable ticket, giving them the right to travel first-class on the Russian and Finland railways free of cost. The excursions arranged, both to precede and succeed the meeting, include a visit to the Urals, or to Esthonia, or to Finland, before the meeting, and to the Caucasus and Crimea after the meeting.

THE work upon "The Ancient Volcanoes of Great Britain," which has engaged Sir Archibald Geikie's attention for some time, will be published in a few days by Messrs. Macmillan and Co. The subject of the former volcanoes of the British Isles has occupied much of the author's time and thought all through his active life. Born among the crags that mark the sites of some of these volcanoes, he was led in his boyhood to interest himself in their structure and history. Since that time he has taken advantage of every opportunity of extending his knowledge of the phenomena they present, by personally examining the volcanic records of our own islands, and the volcanic regions of Europe and Western America. The forthcoming work will realise a long-cherished desire to combine the materials thus accumulated into a general narrative of the whole progress of volcanic action from the remotest geological period down to the time when the latest eruptions ceased. It is dedicated to Prof. Ferdinand Fouqué and M. Michel-Lévy, and will be a very important contribution to geological literature.

DR. NANSEN was present at the meeting of the Royal Geographical Society on Monday, when a paper on "The North Polar Problem" was read by Sir Clements Markham. In the course of some remarks upon the subject of the paper, he said that he thought the most interesting and important result of the

recent expedition is with regard to the extension of land and sea in the north polar region. The whole of the sea to the north of Siberia was very deep, in fact it formed a north polar basin filled with comparatively warm water, and it could be asserted with great certainty that the Pole itself must be situated in that deep sea basin. The fact that the ice was always easily drifting north, indicated that there could not be much land to the north of their route, because if there had been land it must have stopped the drift of the ice in that direction. There were, also, no land birds to be seen flying northwards, whereas if land existed to the north they would have been certain to have seen some birds of that kind. There might, however, be some small islands to the north, where the ice-drift closed in from time to time in order to get into the layers which were noticed. The oldest ice met with in the polar region was probably of five or six years of age. The ice was, on an average, from 10 feet to 12 feet deep. As to the temperature of the water of the polar sea, it was always found to be pretty constant. At the top there was a layer of about 100 fathoms thick, the temperature of which just rose above freezing point, then the temperature began to sink, and just before the bottom was reached it rose again. This fact clearly shows that warm water must run into the polar sea from the south. The warm Atlantic water comes into the sea from the Gulf Stream, and forms a warm surface current there. That is perhaps the most important fact with reference to oceanography which has resulted from Dr. Nansen's expedition. Dr. Nansen concluded his remarks by saying that what is really wanted is not merely to reach the Pole, but more scientific observations from the Arctic regions. He did not think it was difficult to reach the Pole itself. With enough dogs it was quite possible. If 200 dogs were taken, the Pole could certainly be reached; but he did not think it was worth while, and he could not see the importance of it, for they would not bring back sufficient observations, and it would be a waste of time and labour. If they wanted scientific observations from the Arctic regions, there was no better plan than the one he adopted—of going into the ice. The ship was an excellent observatory; it was possible to have all kinds of laboratories on board. If he started again, he would build a better ship than the *Fram;* and if a man were to spend five years in such a ship, he was certain to bring back observations that would pay him many times over. He would be possessed of rich material for forming a good idea of the physical conditions of the North Polar region.

THE geometrical interpretation of complex quantity has hitherto been chiefly associated with the name of Argand; but it would now appear that this mathematician had been anticipated by a Norwegian named Caspar Wessel, who, on March 10 1797, communicated to the Academy of Sciences of Copenhagen a paper entitled, "Om Directionens analytiske Betegning" (on the analytic representation of direction). Caspar Wessel was a land-surveyor, who attained some distinction in his profession, but appears never to have been recognised as a mathematician; and this paper is remarkable both from being his only contribution to mathematical knowledge, and at the same time bearing distinct marks of mathematical genius. Not only did Wessel show how directed quantities could be represented in two-dimensional space by expressions involving $\sqrt{-1}$, but he also gave a theory of algebraic operations involving lines in three-dimensional space, thus anticipating Hamilton's theory of quaternions by nearly fifty years. To commemorate the centenary of the publication of this important paper, a French translation has been issued by the Danish Royal Academy, with prefaces by MM. H. Valentiner and T.-N. Thiele.

REFERRING to the plague in India, the *Lancet* remarks that the reports are, on the whole, more hopeful and promising, those from Bombay city showing a decided improvement. The total plague returns for Bombay city up to the 11th inst. amount to 9032 cases and 7546 deaths. The week's mortality from all causes in Bombay was 1326, as compared with 1484 in the previous week; and the returns for the whole Presidency since the outbreak of the plague up to the 6th inst. amount to 14,856 cases and 12,204 deaths. It will be remembered that many persons were disposed to think that there was some connection between the outbreak of plague and the storage of grain, and Surgeon-Colonel Waters some time ago gave an interesting account of his researches into the origin of plague, in which he adverted to the rat murrain that had been noticed in several of the outbreaks of bubonic disease, and to the plausible hypothesis that the disease might be connected with something affecting the granaries and the storage of the cheaper varieties of grain and millet. Mr. Hankin reports, however, that he has examined a large number of specimens of grain and flour under various conditions, but has been unable to detect the plague microbe in any of them, and that his examination of weevils and of other parasitic insects has also been with negative results. M. Haffkine has been busily occupied in developing a prophylactic and antitoxic serum. It is yet too early to pronounce any opinion on their efficacy, but the antitoxic curative serum has already been tried in many cases of plague with, so far, promising results. Dr. Yersin has prepared a stock of antitoxic serum, and we shall soon know whether the results obtained in India are confirmatory of those which were obtained, by others and himself, in China.

THE Agricultural Research Association does good service by disseminating trustworthy and useful information on agricultural subjects by means of scientific investigation. From the report, just received, we learn that the work done in 1896 was concerned chiefly with the cultivation of oats and the grass crop. With regard to the "dressing" or selection of oats for seed, it has been proved by experiment that, contrary to what might have been anticipated, large seeds afford no ground for expectation of the production of large ultimate plants or heavier crops, nor do they secure any earlier germination. What they do secure is power to reach the surface though deeply deposited, and a stronger briard, which will enable the plants to withstand uncongenial conditions of soil or season at the early stage of growth. The subject was further followed up to find why a large seed does not necessarily tend to produce a large plant. By this inquiry the fact has been found, by an investigation, that the size and strength of the embryo plant within the seed does not bear any relation to the size of the seed; small seeds may often contain larger or stronger embryos than a large seed; the extra size of the seed indicates merely the provision of extra food for the embryo. The production of a strong embryo probably depends rather on the parental influence, a circumstance which opens up an interesting subject that seems worthy of investigation, and one which might be expected to give results of practical value. Other work of the Committee refers to the proper time for harvesting oats, and the cultivation of suitable grasses. It is suggested that grass should lie longer than has hitherto been the practice. The Hon. Secretaries of the Association are:—Mr. Ranald Macdonald, Factor, Cluny Estates; Mr. John Milne, Mains of Laithers, Turriff. The Director of Research is Mr. Thomas Jamieson, 173 Union Street, Aberdeen.

THE presentation of the Albert Medal of the Society of Arts to Prof. D. E. Hughes, F.R.S., has induced our worthy contemporary—*Invention*—to disinter from the past the early history of the microphone. This instrument was invented in December 1877, and was first shown privately, in February 1878, to the officials of the Submarine Telegraph Company. The first demonstration of the discovery was made on May 2, 1878, a

Prof. Hughes' rooms. "Upon that occasion," remarks our contemporary (March 6), "besides the professor, there were present the late Prof. Huxley, Prof. Norman Lockyer, Mr. W. H. Preece, Mr. Conrad W. Cooke, and Mr. Perry F. Nursey. It is an idiosyncrasy with Prof. Hughes that his remarkable inventions have all been worked out with the most simple and commonplace tools. Thus on the occasion referred to the apparatus was of the most primitive character, and, with the exception of a Bell telephone receiver, could not be appraised at more than a few pence. This apparatus had a child's halfpenny wooden money-box for a resonator, on which was fixed by means of sealing-wax a short glass tube, filled with a mixture of tin and zinc, the ends being stopped by two pieces of charcoal to which were attached wires, having a battery of three small Daniell cells—consisting of three small jam-pots—in circuit. The wires were led away to a Bell telephone placed in an adjoining apartment. The money-box, which had one end knocked out, served as a mouthpiece or transmitter, while a Bell telephone was used as a receiver. Sounds scarcely audible, and some absolutely inaudible, to the unassisted ear, were by means of this apparatus delivered with startling loudness through the Bell telephone. Numerous experiments of the utmost importance to physicists were carried out by Prof. Hughes with this apparatus, and with modifications of it, all proving that he had succeeded in producing the simplest and most powerful electric articulating telephone ever known." The first public demonstration of the sensitiveness of the instrument took place at the Royal Society on May 8, 1878.

THE Royal Meteorological Society has for many years past held an exhibition annually, which has been devoted to some special class of meteorological instruments. This year an exhibition of meteorological instruments in use in 1837 and 1897 was arranged, in commemoration of the Diamond Jubilee of H.M. the Queen. The exhibition closed on Friday last. The instruments which were in use in 1837, as might be supposed, were not very numerous, but many of them were somewhat quaint and of great interest. Sir E. H. Verney, Bart., showed an old barometer with a large spirit thermometer, which latter had an arbitrary scale decreasing as the temperature increases, "extream cold" being 90° and "extream hot" 0°. The instruments in use during 1897 were, however, very numerous, and comprised various forms of barometers, thermometers, hygrometers, rain-gauges, anemometers, nephoscopes, sunshine recorders, actinometers, aneroids, electrical and miscellaneous instruments. Many of the instruments were self-recording, and were shown in action. The most interesting exhibit was a railed-off enclosure representing a typical climatological station of the Royal Meteorological Society. This included a Stevenson thermometer screen, fitted with dry bulb, wet bulb, maximum and minimum thermometers; rain-gauge; solar and terrestrial radiation thermometers; sunshine recorder, and earth thermometer; all of which were placed *in situ*. The exhibition also included a number of charts and photographs of great interest, particularly those by Mr. J. Leadbeater, of ice crystals on window-panes. Mr. W. H. Dines showed an experiment illustrating the formation of the tornado cloud, and Mr. Birt Acres exhibited some exceedingly interesting studies of form and movement of clouds and waves projected on the screen by his kinematoscope.

THE Mond gas-producer plant and its application, was the subject of a paper read by Mr. H. A. Humphrey at the Institution of Civil Engineers on March 16. The advantages of gaseous over solid fuel have led to an increasing demand for gas-producers to convert the solid fuel into the gaseous state. Gas-producers have hitherto been constructed to make gas with little regard to by-products, and none have been made to give good results with cheap slack coal, and where the use of gas for gas-engines has been concerned only expensive fuel, such as anthracite or coke, have been found available. But the Mond producer and recovery plant, described by Mr. Humphrey, not only employs cheap bituminous fuel, but recovers from it 90 lbs. of sulphate of ammonia per ton, and yields a gas eminently suitable for use in gas-engines and applicable to all cases of furnace work. The difficulties to be overcome before bituminous slack could be utilised in producers were many; nevertheless Dr. Ludwig Mond has not only succeeded in overcoming them, but has advanced the subject another stage by recovering as ammonia 70 per cent. of the original nitrogen contained in the fuel. The distinguishing features of the Mond process were enumerated, and the manner in which the plant is worked was described in detail.

STATISTICS of the United States Patent Office, just published, show an increase of about 3000 in the number of patents taken out during the last year compared with the year before. The surplus fund of revenues above expenses of the office now exceeds four million dollars.

REFERRING to our note on Prof. F. Plateau's experiments on the mode in which insects are attracted to flowers, Mr. G. W. Bulman calls our attention to a paper by him in the *Zoologist* (vol. xiv. 3rd series, p. 422), and to others published in *Science Gossip* between 1888 and 1892, in which he arrived at a conclusion similar to that of Prof. Plateau, viz. that the bright colour of the corolla does not act as a beacon to attract insects.

WE have received the first part of the division, "Aves," of the great new German zoological work, called "Das Tierreich," which is proposed to contain a descriptive synopsis of all the recent forms in the animal kingdom. The general editor of the whole work (on behalf of the German Zoological Society) is Dr. F. E. Schulze, of Berlin. The editor of the "Aves" is Dr. A. Reichenow, but the present part of that division has been prepared by Mr. Ernst Hartert, director of the Zoological Museum of Tring. There can be no doubt as to the merit of Mr. Hartert's work, which gives all that should be contained in such a synopsis, and no more. But it is a misfortune that German patriotism has rendered it necessary to use German instead of Latin in such a work, which is of a cosmopolitan nature. Multitudes of English and American zoologists, we regret to say, are still unable to read German with any sort of facility, while every one who has been to school understands a little Latin.

ABOUT two years ago Zelinsky found that two hydrocarbons could be obtained from hexamethylene iodide by reduction, the product prepared by means of zinc and hydrochloric acid being different from that got when hydriodic acid was used. Further experiments, of which an account is given in the current number of the *Berichte*, have convinced him that the first of these is the true hexamethylene; whilst the second is identical with the methylpentamethylene, which was first prepared by W. H. Perkin, jun., and P. Freer. The hexamethylene ring, therefore, under the influence of hydriodic acid at 230° changes into a more stable isomeric form. The nature of this change is quite in agreement with Baeyer's celebrated "tension-theory," according to which the pentamethylene ring is more stable than any other. It appears probable, moreover, that the hexahydrobenzene which is formed by the action of hydriodic acid on benzene, and which has long passed for hexamethylene, is in reality methylpentamethylene.

THE additions to the Zoological Society's Gardens during the past week include two Vulpine Phalangers (*Trichosurus vulpecula*, ♂ ♀) from Australia, presented by Mr. W. H. Stather; two Muscovy Ducks (*Cairina moschata*, ♀ ♀) from South

America, presented by Mrs. Dade; two Brown Mud Frogs (*Pelobates fuscus*) from Italy, presented by Count M. Peracca; an Indian Elephant (*Elephas indicus*, ♀) from India, a Rose-crested Cockatoo (*Cacatua moluccensis*) from Moluccas, deposited; a Chimachima Milvago (*Milvago chimachima*), two Violaceous Night Herons (*Nycticorax violaceus*) from South America, a Common Quail (*Coturnix communis*) captured at sea, a Common Rhea (*Rhea americana*) from South America, a Bornean Gibbon (*Hylobates muelleri*, ♀) from Borneo, purchased.

OUR ASTRONOMICAL COLUMN.

THREE BRILLIANT STELLAR SYSTEMS.—Prof. T. J. J. See, with the aid of the 24-inch refractor of the Lowell Observatory, in Mexico, has recently discovered (*Astr. Journal*, No. 396) three objects which "may be regarded as amongst the most splendid systems in the heavens." The first, discovered in January last, is α Phœnicis, its position for 1900 being R.A. 0h. 21m. 19·5s., decl. −42° 50′ 48″·1. The primary of this double has a magnitude of 2·4; the companion being as faint as a thirteenth mag. star. This inequality, combined with the deep orange or reddish colour of α Phœnicis, renders the system both striking and difficult. The mean of some measures made for determination of the position of the components was 1897·041, pos. angle 272°·7, dist. 9″·73. The second of these objects, also a very southern star, is μ Velorum with a magnitude of nearly 3, the companion being 11, of a purplish colour and very near the large star. [R.A. 10h. 42m. 28s., decl. −48° 53′ 31″ (1900)]. This system is described as one of the most extraordinary in the heavens, and likely to have a very large orbital motion. Measurements of position gave for 1897·059, pos. angle 62°·7, dist. 2″·54. The third and last of these objects, η Centauri,' situated at R.A. 14h. 29m. 10s., and decl. −41° 42′ 59″ (1900). The components are of magnitude 2·5 and 13·5, being yellow and purple in colour. The system is described as extremely difficult, requiring a powerful telescope to see it. The relative positions of the components is given for 1897·051, as pos. angle 270°·1, dist. 5″·65.

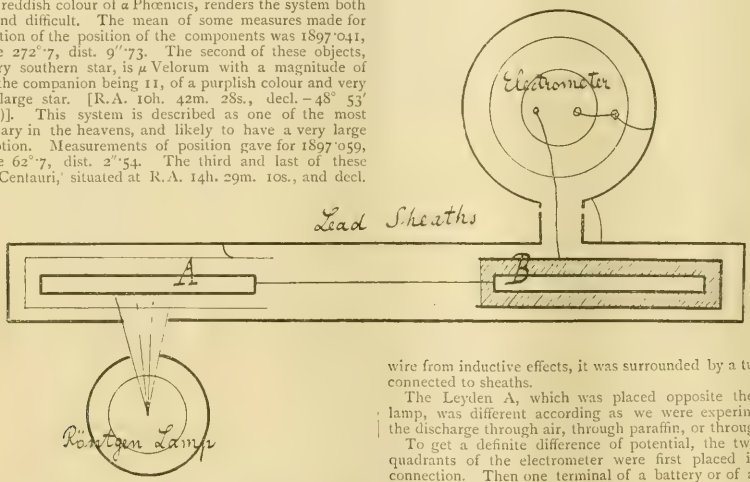
THE COMPANION TO PROCYON.—To those who wish to seek for the companion to Procyon, Prof. Schaerberle's description of the method he adopts (*Astr. Nachr.*, No. 3410) in observing this faint companion will prove of service. Owing to its very close proximity to Procyon, the companion can only be seen when the observing conditions are at their best. If a good objective be employed the aperture should not be reduced, but a cap fitted over the eyepiece is found most serviceable. For Prof. Schaeberle's measures an eyepiece magnifying 500 diameters was employed, the aperture of the cap over the eyepiece being about 1·6 millimetres. The magnitude of this companion is estimated as fully equal to a twelfth-magnitude star, and when the seeing is good it is "as easily and accurately measured as the satellite Phobos when Mars is in opposition." Sirius' companion is estimated as being two or three magnitudes brighter than that of Procyon, and is also being regularly observed at the Lick Observatory, the same means—namely, cap over the eyepiece—being employed.

ON THE INFLUENCE OF RÖNTGEN RAYS IN RESPECT TO ELECTRIC CONDUCTION THROUGH AIR, PARAFFIN, AND GLASS.[1]

WE have in previous papers described experiments respecting electric conduction when Röntgen rays fall on metals, positively or negatively electrified to potentials of two or three volts. We found that although air is rendered conductive, paraffin and glass are not rendered sensibly conductive when the differences of potential concerned are not more than two or three volts per centimetre of air, or per centimetre of paraffin, or per half-millimetre of glass.

We have now to describe an extension of the investigation to much higher voltages, in which we use an arrangement of two (quasi) Leyden jars, A and B, with their inside coatings connected together. The outside coating of A was connected to sheaths, the outside of B to the insulated terminal of the electrometer. In all the experiments to be described, B remained the same.

It consisted of a cylindrical lead can, 25 cms. long, 4 cms. diameter. A metal bar about 1 cm. diameter, 25 cms. long, was supported centrally on paraffin filling the whole space between it and the containing lead. This metal bar was connected by a wire to the internal coating of A. To protect this



wire from inductive effects, it was surrounded by a tube of lead connected to sheaths.

The Leyden A, which was placed opposite the Röntgen lamp, was different according as we were experimenting on the discharge through air, through paraffin, or through glass

To get a definite difference of potential, the two pairs of quadrants of the electrometer were first placed in metallic connection. Then one terminal of a battery or of an electrostatic inductive machine was connected to the internal coatings of the jars, and the other terminal to sheaths. The difference of potential produced was measured by a multicellular voltmeter in the case of differences under 500 volts, and on a vertical single vane voltmeter for higher differences.

When the desired difference of potential had been established, the metallic connection of the battery or electric machine with the internal coatings of A and B was broken, and this charged body left to itself. To find the loss due to imperfect insulation, the pair of quadrants in metallic connection with the outside coating of B was insulated in the ordinary way, and the deviation of the electrometer reading from the metallic zero per half-minute was observed. To find the loss when the rays were acting, the two pairs of quadrants were again placed in metallic connection, the Röntgen lamp set a-going, then the pair of quadrants connected to the outside coating of B was insulated from the other pair, and the deviation from metallic zero again observed per half-minute.

In the experiments with air, the Leyden A consisted of an aluminium cylinder, 16 cms. long, 3 cms. in diameter. This cylinder projected beyond the lead tube, and was connected to sheaths. The insulated metal inside it, which was a flat strip

[1] By Lord Kelvin, Dr. J. Carruthers Beattie, and Dr. M. Smoluchowski de Smolan. Read before the Royal Society of Edinburgh, March 1.

of aluminium, about 10 cms. long and 1½ cms. wide, cut from the same sheet as the surrounding aluminium tube, was supported at one end by a small piece of paraffin so placed as to be out of reach of the action of the Röntgen lamp. The rays from the lamp were allowed to pass from a lead cylinder surrounding it by a small hole about ·3 of a square cm. in area. They fell on the aluminium sheath transparent to them, and rendered the air between it and the insulated aluminium within conductive.

We tried various differences of potential, ranging from a few volts to 2200 volts. In one series of experiments we charged the insulated metal to −97·5 volts, and then disconnected the battery electrodes. The lamp was then set a-going, and the electrometer deviation taken each half-minute for a minute and a half with one pair of quadrants insulated. The rays were then stopped, the quadrants metallically connected, and metallic zero again found. Then the reading during another period of one and a half minutes, with the rays acting, was observed, and so on until no deviation from the metallic zero of the electrometer was found with one pair of quadrants insulated, and the rays falling on the aluminium outside coating of the Leyden A. The sensibly complete discharge thus observed took place in about a quarter of an hour. We found that the rate of deviation from the metallic zero was the same as the difference of potential fell from −97·5 volts to about −4 volts. With differences of potential of −930, −1750, and −2000 volts the rate of deviation was not appreciably greater than with ± 20 volts.

This confirms and extends, through a very wide range of voltage, the interesting and important discovery announced by J. J. Thomson and McClelland, in their paper in the Cambridge Philosophical Society *Proceedings* of March 1896, to the effect that the conduction of electricity through air under influence of the Röntgen rays is almost independent of the electric pressure when it exceeds a few volts per centimetre.

In the experiments on paraffin, the outside coating of the Leyden A consisted of an aluminium cylinder 27 cms. long, 4 cms. diameter, connected to sheaths. A metal bar about 1·75 cms. in diameter, and 30 cms. long, supported centrally on paraffin filling the whole space between it and the aluminium sheath, constituted the inside coating. With this arrangement we made experiments with differences of potential of ± 94, ± 119, ± 238, − 2000, + 2500, and − 2400 volts. At none of these potentials did we find any perceptible increase of conductance produced by the Röntgen rays above the natural conductance of the paraffin when undisturbed by them.

In the experiments with glass, the Leyden A consisted of a glass tube silvered on the inside. The inside silvering was placed in metallic connection with the inside coating of B. That part of the glass tube which projected beyond the lead sheath was covered with wet blotting-paper connected to the sheaths. We observed the behaviour of glass under the Röntgen rays at differences of potential of + 800, + 1500, + 2000 volts. We found no indication of increased conductance due to the rays at these voltages.

We are forced to conclude that the experiments described by J. J. Thomson and McClelland do not prove any conductance to be induced in paraffin or glass by the Röntgen rays. It seems to us probable that the results described in their paper —pages 7 and 8—are to be explained by electrifications induced on surfaces of glass or of paraffin in contact with air rendered temporarily conductive by the Röntgen rays.

THE INTRODUCTION OF BENEFICIAL INSECTS INTO THE HAWAIIAN ISLANDS.[1]

FEW countries have been more plagued by the importation of insect pests than the Hawaiian Islands; in none have such extraordinary results followed the introduction of beneficial species to destroy them. By far the most conspicuous of the former class, and hitherto the most injurious, have been the scale-insects. The number of species of this group, which have spread throughout the islands, is remarkable, and not less so the enormous multiplication of individuals of many or most of these species.

[1] Notes on the result of introducing predatory and parasitic insects into the Hawaiian Islands for beneficial purposes. Communicated by the Secretary of the Committee, appointed by the Royal Society and British Association, for investigating the Fauna of the Sandwich Islands.

The first importation of *Coccinellidæ* to destroy these hordes was made in 1890, when *Vedalia cardinalis*, Muls., a native of Australia, was sent over by Mr. Albert Koebele. At that time many trees were in a deplorable condition from the attacks of *Icerya*, monkey-pod trees being particularly badly infested—so much so that they were being largely cut down, as the only resource. The *Vedalia* was a complete success; it became perfectly naturalised, increased prodigiously for a time, practically cleared the trees, and then, as the *Icerya* became comparatively scarce, decreased in numbers; while at the present time it is evident that the number of the scale and its destroyer has arrived at a fixed proportion. Previously to its introduction here the same ladybird had done excellent service in the fruit orchards of Lower California.

The complete success of this first experiment was followed by the engagement of Mr. Koebele by the Hawaiian Government and planters for a term of years, to contend against other plagues no less serious than the *Icerya*. The wisdom of this course cannot be too highly commended, when compared with the indifference shown by the countries similarly circumstanced, and is a set-off against the reckless importation of infected plants which had been allowed in former years. Mr. Koebele, after seeing the wants of the country, with his unrivalled knowledge of the habits of *Coccinellidæ*, introduced numbers of other species in 1894, many of which, no doubt, failed to establish themselves, while a considerable number (how many is yet uncertain) have become completely naturalised, and done splendid service.

Before mentioning these, it may be said that the two chief products of the islands are sugar (which until lately has been far the most important export) and coffee, the cultivation of which has lately enormously increased. There is also a considerable amount of fruit grown; and this, too, is lately increasing. All these industries have been continually threatened with destruction from imported insects. The Rev. T. Blackburn, who studied the insects of the islands during six years—now nearly twenty years ago—wrote that the fruit trees were afflicted with incurable blight. Coffee plants were introduced in 1825. Its cultivation formed quite an industry in the middle of the century on Kauai, where only it was systematically cultivated; its growth was finally abandoned there in 1856, owing to the ravages of blight, said to have been imported in 1850. The sugar-cane has been, and is, attacked not only by scale-insects and *Aphides*, but by several other creatures of quite different orders.

To return now to the ladybirds: one of the most useful has been *Coccinella repanda*, Thun. (from Ceylon, Australia, China, &c.) which feeds on *Aphides*. The services of this species cannot be over-estimated. On Kauai recently the cane was so much attacked by an *Aphis* as to cause considerable alarm. On visiting the locality the *Coccinella* was found to be already present, breeding in such numbers as to leave little doubt that the plants would be soon cleared. On the same island, on another occasion, I saw the fruit trees (especially orange and lime) in a beautiful garden in a most deplorable condition from the attacks of *Aphis* and scales. Very few ladybirds could be found after a careful search. The owner was for spraying the trees, but, seeing their condition could not be much worse, I advised him to wait and give the beetles a chance. In a few weeks these were swarming; and when I returned, after six months, the infested trees were all in perfect condition, full of fruit and flower. Not less numerous than the preceding is a *Cryptolæmus* (*C. montrouzieri*) introduced from Australia, and thoroughly naturalised. It attacks the highly injurious species of *Pulvinaria*. When I visited the Kona district of Hawaii in 1892, many of the trees were literally festooned with the masses of this pest, and appeared on the point of being totally destroyed. In 1894 the ladybirds were sent there, and very soon had entirely changed the condition of things, and the affected trees speedily recovered. To show the vast increase of this species of ladybird, I may state that in June of the present year, many large trees in the city of Honolulu had several square feet of their bark entirely hidden by the larvæ, which formed great white masses, presenting such an extraordinary appearance that I much regret not having obtained photographs of some of the trees. At the present time this species and *Coccinella repanda* are far the most conspicuous and abundant of the introduced *Coccinellidæ*, either of them far outnumbering even the most abundant native insects. Their wide distribution is remarkable, for not only are they all over the lowlands, but throughout the mountain forests as high as four or five thousand feet above sea-level; indeed, the *Coccinella* is still higher up beyond the limits of

the forest proper. Other introductions, some of which are extremely abundant, may be briefly noticed. The beautiful *Orcus chalybeus*, from Australia, is now widely spread and very common, feeding on *Lecanium*, *Pulvinaria*, *Diaspis*, &c. *Rhizobius ventralis*, Muls., from China and Ceylon, attacks that most abundant scale *Lecanium longulum*, and other species. *Chilocorus circumdatus*, from China and Ceylon, breeds freely on scales in Honolulu. Trees literally covered with *Mytilaspis* were entirely cleaned. Even the old dry scales were turned over in the search for food. *Platyomus livudigaster* has bred freely on orange *Aphis* in the city. *Scymnus debilis*, which in California feeds on *Dactylopius*, has become entirely naturalised. Other introductions, which have bred in the Islands, are *Chilocorus bivulnerus*, *Leis conformis*, *Synonycha grandis*, and *Novius Koebelei* (Fig., Rep. on Import. of Par. and Pred. Ins., by State Board of Horticulture, Sacramento, 1892.) There is little doubt that[1] other introduced species will turn up, when the city gardens and suburbs are systematically searched. Before the introduction of the species above mentioned, the only known Hawaiian *Coccinellidæ* were a few species (probably endemic) of *Scymnus* and *Coccinella abdominalis*, the latter, no doubt, accidentally imported from America many years ago. Unfortunately this species is attacked by a hymenopterous parasite, a *Braconid*, *Centistes americana*, Riley, which may interfere with the splendid work of *C. repanda*. The presence of this parasite is the more to be deplored, as such care was taken to exclude parasitised specimens when the introductions were made. This was very necessary, as the ladybirds seem very liable to the attack of parasitic Hymenoptera, especially the Australian species.

It is very pleasing to be able to refer to such successful results in the Hawaiian Islands, as in the United States Mr. Koebele's work has met with a good deal of adverse criticism. But it is not only by the introduction of ladybirds that Mr. Koebele has done such signal service, for he has had many other insect pests to contend with, which it is beyond the power of these to affect, attacking, as they do, but a very small portion of the insect world. In many parts of the islands, the bananas and palm-trees have been severely attacked by the larva of a species of *Pyralidina*. There is little doubt that in course of time this plague will be entirely kept under by a fine Chalcid (*Chalcis obscurata*, Walk.), introduced from China and Japan, which has already multiplied enormously at the expense of these caterpillars—so much so, indeed, that in many localities the trees have now entirely recovered. Again, within the last few years a Lamellicorn beetle (*Adoretus umbrosus*) has been introduced from Japan. This insect speedily multiplied prodigiously, and soon destroyed nearly every rose-tree in Honolulu, and subsequently attacked the foliage of many other trees. The cultivation of roses—once a feature of the city—became impossible, while a remedy seemed hopeless. One day, however, Mr. Koebele discovered a parasitic fungus, and by cultivation of this, and infecting healthy beetles, soon spread it far and wide. Whether the fungus will prove entirely effective is not at present certain, but in any case it will be a most useful aid. The writer has seen the ground under trees which were attacked, literally strewn with dead beetles—all killed by the fungus—and beneath the surface of the soil the larvæ had likewise perished. It is at least certain, therefore, that myriads of the beetles were destroyed very shortly after the fungus was spread around by the individuals that had been infected.

It becomes natural to ask why the success of the imported beneficial insects has been so pronounced here, while in other countries it has been attained in a comparatively small measure. The reason, I think, is sufficiently obvious. The same causes which have led to the rapid spread and excessive multiplication of injurious introductions, have operated equally on the beneficial ones that prey upon them. The remote position of the islands, and the consequently limited fauna, giving free scope for increase to new arrivals, the general absence of creatures injurious to the introduced beneficial species, and the equability of the climate, allowing of almost continuous breeding, may well afford results which could hardly be attained elsewhere on the globe. The keen struggle for existence of continental lands is comparatively non-existent, and, so far as it exists, is rather brought about by the introduced fauna than by the native one.

In conclusion, I cannot help turning to the darker side of the picture. What will be the result of all these importations on the endemic fauna? The introduction of many other species—parasitic and predaceous—is contemplated, and will be performed. That success, from an economic point of view, will be attained there is little doubt, and while industries are threatened, or even the gratification of æsthetic tastes, it is certain that no consideration will be given to the native fauna. When even now the ladybirds are affecting the latter, what will be the result of the introduction of more widely predaceous species? The effect of the former is not imaginary, but proven. In June 1895, in a lovely forest in Hawaii—5000 feet above sea-level—I found the native trees much affected by a black *Aphis*. By beating these trees the blight came down in abundance, and amongst them various fine species of endemic *Chrysopa* and *Hemerobius*, predatory creatures. One or two introduced ladybirds were also noticed. By September the ladybirds were in thousands, the blight and native insects in small numbers. In August 1896 not an *Aphis* was to be found, and only one or two stray specimens of ladybirds, as one may find anywhere throughout the forests. They had done their work and disappeared. This is a high testimonial as to the capabilities of the beetles, and as the existence or non-existence of Hawaiian *Chrysopa* is not likely to be regarded by people at large, and seeing that sooner or later the greater part of this most interesting native fauna is, under any circumstances, in all probability doomed to extinction, it only remains to wish Mr. Koebele a success in the future equal to that which he has already attained.

Honolulu, H.I., November 1896. R. C. L. PERKINS.

[1] Since writing the above several other species have been found, which have evidently bred in the country.

MARINE ORGANISMS AND THE CONDITIONS OF THEIR ENVIRONMENT.[1]

THE ocean may be divided into two great biological regions, viz. the superficial region, including the waters between the surface and a depth of about 100 fathoms, and the deep-sea region extending from the 100 fathoms line down to the greatest depths. The superficial region may be subdivided into two provinces, viz. the shallow-water or neritic province around the land masses where the depth is less than 100 fathoms, and the pelagic province, embracing the superficial waters of the ocean basins outside the 100 fathoms line; these two provinces contrast sharply as regards physical conditions, which are of great variety in the neritic province, and very uniform over wide areas in the pelagic province.

Temperature is a more important factor in determining the distribution of marine organisms, mostly cold-blooded, than in the case of terrestrial species, mostly warm-blooded and air-breathing animals, the distribution of which depends rather upon topographical features than upon climatic conditions.

A map was exhibited showing the range of temperature in the surface waters of the ocean all over the world, and indicated northern and southern circumpolar areas with a low temperature and small range (under 10° F.), and an almost circumtropical area with a similar small range but high temperature; in temperate regions the range is greater, the areas of greatest range (over 40° F.) being found off the eastern coasts of North America and of Asia and south of the Cape, due to the mixture of currents from different sources, which sometimes causes the destruction of enormous numbers of marine invertebrates and fishes.

The pelagic tropical waters of the ocean teem with various forms of life, of which probably 70 to 80 per cent. function as plants, converting, under the influence of sunlight, the inorganic constituents of sea-water into organic compounds, thus forming the original source of food of marine animals both at the surface and at the bottom of the sea.

The number of species living in the pelagic waters of the tropics may greatly exceed the number in polar waters, where, on the other hand, there is often a great development of individuals, so that there is probably a greater bulk of organic matter in the cold polar waters than in the warm tropical waters. The rate of animal metabolism is slower at a low than at a high temperature, and organisms inhabiting tropical waters probably pass through their life-history much more rapidly than similar organisms living in polar regions. Carbonate-of-lime-secreting organisms are most abundant in the warm tropical waters, decreasing in numbers towards the polar regions, and it has been shown that the precipitation of carbonate of lime from solution in sea-water takes place much more rapidly at a high

[1] An address delivered at the Royal Institution by Dr. John Murray, F.R.S.

temperature. The pelagic larvæ of bottom-living species are always present in the warm surface waters of the tropics, sometimes growing to an enormous size; but they are absent from the cold polar waters and in the deep sea, where the majority of the bottom-living species have a direct development.

The Arctic fauna and flora, both at the surface and at the bottom, resemble the Antarctic fauna and flora, and a large number of identical and closely-related species are recorded from the two polar areas, though quite unknown in the intervening tropical zone.

The boundary line between the deep-sea region and the neritic province is marked out by what has been called the "mud-line," where the minute organic and inorganic particles derived from the land and surface waters find a resting place upon the bottom, or serve as food for enormous numbers of crustacea, which in their turn are the prey of fishes and the higher animals; this mud-line, in fact, appears to be the great feeding-ground in the ocean, and its average depth is about 100 fathoms along the borders of the great ocean basins.

The majority of deep-sea species are mud eaters; some are of gigantic size; some are armed with peculiar tactile, prehensile, and alluring organs; some are totally blind, whilst others have large eyes and are provided with a kind of dark lantern for the emission of phosphorescent light. The deep-sea fauna does not represent the remnants of very ancient faunas, but has rather been the result of migrations from the region of the mud-line in relatively recent geological times.

The *Challenger* investigations show that species are most abundant in the shallow waters near land, decreasing in numbers with increasing depth, and especially with increasing distance from continental land.[1] This is true as a general rule, especially of tropical waters, but in polar regions there are indications of a more abundant fauna in depths of 50 to 150 fathoms than in shallower water under 50 fathoms.[2]

The various points touched upon regarding the distribution of marine organisms, might be explained on the hypothesis that in early geological times there was a nearly uniform high temperature over the whole surface of the globe, and a nearly uniformly distributed fauna and flora; and that with the gradual cooling at the poles, species with pelagic larvæ were killed out or forced to migrate towards the tropics, while the great majority of the species which were able to survive in the polar areas were those inhabiting the mud-line. The uniform physical conditions here referred to might be explained by adopting the views of Blandet[3] as to the greater size and nebulous character of the sun in the earlier ages of the earth's history.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Dr. J. N. Langley, F.R.S., and Mr. A. C. Seward, Lecturer in Botany, have been appointed additional members of the Degree Committee of the Board for Biology.

Mr. F. F. Blackman, of St. John's College, has been appointed University Lecturer in Botany.

The special numbers of the *University Reporter* containing the Report of the Syndicate on Degrees for Women, and the speeches made in the three days' discussion thereupon in the Senate House, can be obtained (price 7*d.*) by application to the University Press, Cambridge.

DR. ALEXANDER J. C. SKENE, president of the Medical College of the Long Island College Hospital of Brooklyn, has received the degree of LL.D. from the University of Aberdeen, his native city.

MR. JOHN D. ROCKEFELLER has given 40,000 dollars to Mount Holyoke College, in Massachusetts. This is a college for women, which a few months ago met with heavy loss by the burning of its buildings.

MRS. E. A. STEVENS, widow of the founder of the Stevens Polytechnic Institute, has given to that Institute property valued at 30,000 dollars, since the quarter-century celebration held a few days ago.

[1] See "*Challenger* Reports," "A Summary of the Scientific Results," by John Murray, pp. 1430-1436, 1895.

[2] See Murray, "On the Deep and Shallow-Water Marine Fauna of the Kerguelen Region of the Great Southern Ocean," *Trans. Roy. Soc. Edin.*, vol. xxxviii. p. 343, 1896.

[3] *Bull. Soc. géol. de France*, sér. 2, t. xxv. p. 777, 1868.

IT is stated that M. Solvay, who owns large industrial establishments in the neighbourhood of Nancy, has given 100,000 francs to the university of that city, for the purpose of erecting a chemical and electrical laboratory.

THE Senate of the University of Glasgow have resolved to confer the honorary degree of LL.D. upon Mr. J. Wolfe Barry, C.B., F.R.S., President of the Institution of Civil Engineers, London; Prof. John M'Cunn, Professor of Philosophy in University College, Liverpool; and Prof. W. Ramsay, F.R.S., Professor of Chemistry in University College, London.

A BLUE-BOOK just published shows that the total amount expended by local authorities on technical education during the year 1894-5 was 737,809*l.* 5*s.* 4*d.*; and that the estimated total expenditure on technical education during the year 1895-6 was 793,507*l.* 17*s.* 7*d.* These amounts are exclusive of the sums allocated to intermediate and technical education under the Welsh Intermediate Education Act, and amounting to 42,861*l.*

THE following are among recent announcements:—Dr. Hans Lemke to be assistant at the meteorological and magnetic observatory at Potsdam; Prof. Simmara to be professor of physiological psychology in the Government School of Science at Madrid; Dr. E. Vischer, associate professor of botany at Bern, to be professor and director of the Botanic Gardens there; Dr. Ross to be curator of the Botanical Museum at Munich; Dr. J. Y. Mackay, professor of anatomy, to be principal of the University College, Dundee; Prof. P. Baccarini to be professor of botany in the University of Catania; Dr. O. Kruch to be professor at the agricultural experiment station in Perugia; Dr. W. Felix to be associate professor of anatomy in the University of Zürich.

A COMPARISON of the number of hours devoted to different departments in four Universities in the United States is made in *Science*. The following table shows the relative attention given to different branches of knowledge.

	Harvard.	Cornell.	Yale.	Princeton.
Classics	8·7	8·0	24·2	22·6
European languages	22·8	18·8	14·5	12·4
English	16·8	16·3	10·9	11·3
Political science	9·9	6·5	11·2	9·6
History	14·3	8·2	10·4	
Mathematics	4·4	6·6	9·6	19·4
Philosophy	6·1	7·7	8·9	8·6
Natural science	10·2	23·5	8·1	8·8

It is pointed out by *Science* that Yale and Princeton agree somewhat closely in the distribution of studies, except for the excess in mathematics at Princeton. Harvard and Cornell also agree to a considerable extent, but Cornell devotes one-fourth of the entire time (the figures refer to the academic department) to science. It is noteworthy that in the Senior year at Princeton, when the studies become elective, only 3·8 per cent. of the time is given to the classical languages, and 15·1 per cent. to natural and physical sciences. The classical languages evidently only hold their position at Yale and Princeton through compulsion. European languages tend to take their place in large measure with some gains by English and the sciences.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 4.—"The Palæolithic Deposits at Hitchin and their Relation to the Glacial Epoch." By Clement Reid, F.L.S., F.G.S., of the Geological Survey of the United Kingdom. Received February 15.

In continuation of the researches at Hoxne, communicated last autumn to the British Association, excavations and borings have been made at Hitchin, with the object of ascertaining whether the conclusions arrived at are supported by the study of a fresh locality. The results obtained at Hitchin are thoroughly in accord with those obtained at Hoxne. At each place brick-earth with Palæolithic implements can be proved to overlie the latest boulder clay of the district. At Hoxne the Palæolithic deposits were shown to be separated from the boulder clay by two distinct alluvial deposits, the newer of which yields an arctic flora, the older a temperate one. The arctic plants have not yet been discovered at Hitchin, but abundance of temperate species occur in the older alluvium.

At each locality the same story is told. Some time after the passing away of the ice the land stood higher than now, so that

the streams had a greater fall and valleys were cut to a somewhat greater depth. Then the land sank and the valleys became silted up with layer after layer of alluvium, to a depth of at least 30 feet, the climate remaining temperate. The next stage, when an arctic flora reappeared, is only represented at Hoxne. The third stage in the infilling of the valleys is shown in the curious unstratified decalcified brick-earth with scattered stones and Palæolithic implements, identical in character at Hitchin, Hoxne, Fisherton, and other localities, which irresistibly suggests a mingling of wind-transported material and rain-wash.

It may be pointed out that if this hypothesis of the origin of the Palæolithic brick-earth during the reign of "steppe" conditions be accepted, it will account for the non-correspondence of the ancient channels with the present valleys, a thing very difficult to explain if the infilling were caused by ordinary fluviatile action. If the Palæolithic brick-earth is equivalent to the Palæolithic loess of the ancient deserts in central Europe, we can understand how during this period of cold drought the smaller streams ceased to flow and their valleys became so filled with rain-wash and dust that when a moister climate recurred the streams had to seek new channels.

March 11.—"The Origin and Destination of certain Afferent and Efferent Tracts in the Medulla Oblongata." By J. S. Risien Russell, M.D., M.R.C.P.

In attempting to ascertain the origin and destination of some of the tracts of nerve fibres which exist in the medulla oblongata by the degeneration method, many of these tracts were divided, and among them the posterior connections of the cerebellum, and, similarly, certain nerve centres situated in the medulla were severed from their connections with the rest of the organ.

Among other results obtained by these experiments the author finds, in support of his previous contentions based on results obtained by ablation of the cerebellum, that while paths derived from the spinal cord can be traced directly to the cerebellum, no direct path can be traced from the cerebellum to the spinal cord. He, however, finds that an indirect path of this kind exists, and that the first portion of it is what was formerly regarded as a sensory tract passing from the medulla oblongata to the cerebellum, but which is in reality a path from the cerebellum to a special group of nerve cells in the medulla known as Deiters' nucleus, from which another tract of fibres originates which can be traced throughout the whole length of the spinal cord, and which becomes connected with the anterior horn of the same side, and to a lesser degree with that of the opposite side.

The author further finds that there are other important connections of these nerve cells known as Deiters' nucleus, with the corpora quadrigemina, superior olivary bodies and the cervical region of the spinal cord by way of the posterior longitudinal bundles. The cerebellum is thus brought into relationship with these various nerve centres in a way that suggests that these connections may have important bearings in regard to the movements of the head and eyes.

Chemical Society, March 4.—Mr. A. G. Vernon Harcourt, President, in the chair.—The following papers were read:—Some hydrocarbons from American petroleum. (1) Normal and iso-pentane, by S. Young and G. L. Thomas. By fractional distillation of "pentane" from American petroleum, the authors have obtained pure normal and iso-pentane; the boiling points under normal pressure are 36°3° and 27°95° respectively.—The vapour pressures, specific volumes and critical constants of normal pentane, with a note on the critical point, by S. Young. The critical data of normal pentane are 197°2°, 25100 mm., and 4°303 c.c.; the thermal and other data obtained lead to the conclusion that in the liquid state and at the critical temperature the molecules of pentane are simple ones, as in the gaseous state.—On the freezing-point curves of alloys containing zinc, by C. T. Heycock and F. H. Neville. The melting-point curves of binary alloys of zinc with cadmium, aluminium, tin and bismuth have been examined and the compositions of the eutectic mixtures determined; dilute zinc solutions containing lead, thallium, antimony and magnesium were also examined. The freezing point of zinc is depressed by admixture with the metals named above, but is raised by addition of copper, gold, or silver.—The oxides of cobalt and the cobaltites, by A. H. McConnell and E. S. Hanes. The authors describe the preparation of alkali cobaltites, and show that cobalt forms an oxide CoO_2, an acid H_2CoO_3, and a series of alkali salts of the type of potassium cobaltite K_2CoO_3.—A new synthesis in the sugar group, by H. J. H. Fenton. Glycollic aldehyde condenses when heated in a vacuum, giving a sweet-tasting gum of the composition $C_6H_{12}O_6$; this "sugar" yields a hexosazone $C_{18}H_{22}N_4O_4$, and is not fermented by yeast. When heated it loses water, apparently yielding compounds of the compositions $C_{12}H_{22}O_{11}$ and $C_6H_{10}O_5$.—The dinitrosamines of ethyleneaniline, the ethylene toluidines and their derivatives, by F. E. Francis.—Contribution to the knowledge of the β-ketonic acids, Part v., by S. Ruhemann and A. S. Hemmy.—Enantiomorphic forms of ethylpropylpiperidonium iodide, by Miss C. de B. Evans. Ethylpropylpiperidonium iodide, $C_5H_{10}EtPrNI$, crystallises in right- and left-handed enantiomorphous crystals just as sodium chlorate does.—Further note on ketopinic acid—pinophanic acid, by W. S. Gilles and F. F. Renwick. Ketopinic acid yields a hydroxime and a monobrom-derivative, and when fused with soda is converted into a dibasic acid $C_{10}H_{16}O_4$, which is termed pinophanic acid.—A synthesis of citric acid, by W. T. Laurence. Ethylic citrate is synthetically obtained by the condensation of ethylic bromacetate with ethylic oxalylacetate in presence of zinc as indicated by the following equations: (1) $COOEt.CH_2Br + COOEt.CH_2.CO.COOEt + Zn = COOEt.CH_2.C(OZnBr)(CH_2.COOEt).COOEt$. (2) $COOEt.CH_2.C(OZnBr)(CH_2.COOEt)COOEt + H_2O = COOEt.CH_2.C(OH)(CH_2.COOEt).COOEt + ZnO + HBr$.

Linnean Society, March 4.—Dr. A. Günther, F.R.S., President, in the chair.—Mr. W. Carruthers, F.R.S., exhibited, with the aid of lantern-slides, a series of portraits of Linnæus, and gave some account of the history of each. In the course of a tour which he had made in Sweden and Holland, he had been fortunate enough not only to see the original paintings, but also to obtain photographs of them, so that he was now able to exhibit exact copies. Putting aside "supposed portraits," and such as might be termed "fancy portraits" having no claim to authenticity, he had satisfied himself of the existence of eight that were certainly painted or drawn from life, and had been copied more or less frequently by different engravers. The earliest of these was painted by Hoffman in 1737, while Linnæus was working for his patron Cliffort at Hartecamp, and represents him at the age of thirty in the picturesque dress in which he travelled through Lapland. Of the next portrait, an engraving by Ehrensverd in 1740, no original is known to exist. In 1747, at the age of forty, two pencil sketches of Linnæus, one being a full length, were made by Rehn; and five years later a beautiful pastel was executed by Lundberg. Scheffel in 1755 painted him at the age of forty-eight; and this portrait is preserved at Hammarby in the house of Linnæus, now public property under the care of Prof. Fries of Upsala. Then came the medallion by Inlander, executed in 1773, of which a copy (one of three) is in possession of this Society. The following year, when Linnæus was sixty-seven years of age, his portrait was painted by Krafft, and was placed originally in the Medical College of Stockholm, of which Linnæus was one of the founders. It was supposed to be lost, but had been removed to the Royal Academy of Sciences in Stockholm, where Mr. Carruthers discovered it. The latest portrait was that by Roslin, painted in 1775, when Linnæus was in his sixty-eighth year. A fine copy of this by Pasch, presented to Sir Joseph Banks, and given by him to Robert Brown, now hangs in the Society's library.—Dr. W. B. Benham read a paper on some new species of earthworms belonging to the genus *Perichæta* from New Britain and elsewhere, with remarks on certain diagnostic characters of the genus.—On behalf of Mr. W. G. P. Ellis, Demonstrator in Botany at the University Botanical Laboratory, Cambridge, the Secretary gave the substance of a paper "On a *Trichoderma* Parasitic on *Peltia epiphylla*."

Geological Society, March 10.—Dr. Henry Hicks, F.R.S., President, in the chair.—Volcanic activity in Central America in relation to British earthquakes, by A. Gosling, H.M. Minister and Consul-General in Central America. The author of the communication points out that the volcano of Izalco, in the Republic of Salvador, which has been in active eruption for over one hundred years, suddenly ceased to be so within a fortnight of the period at which the communication was sent (December 20, 1896), and he notes the occurrence of seven shocks of earthquake in England on December 17, 1896. He quotes remarks concerning the volcano, which were contributed by him to the *North American Review* in January 1896.—The red rocks near Bonmahon on the coast of Co. Waterford, by F. R. C. Reed. The rocks considered in this paper have been regarded by some authorities as deposits interstratified with the Lower Palæozoic rocks of the district, while others have maintained that they are of Old Red Sandstone age. It was the object of the author

to show the correctness of the latter supposition, and he brought forward evidence to prove that the red rocks rest unconformably upon the Lower Palæozoic rocks, or are faulted against them, and that the breccias of the red rocks contain fragments of the Lower Palæozoic rocks, and also of intrusive rocks which break through the latter. The red rocks also resemble deposits which are known to be of Old Red Sandstone age.—On the depth of the source of lava, by J. Logan Lobley. The author contended that lava could not have been brought to the surface from a depth of thirty miles, as fissures which would serve as conduits could not exist at that depth, and, moreover, the lava would be consolidated before it reached the surface, owing to contact with cool rock for a considerable period. He argued that the pressure of the overlying rocks would cause the rocks even at a depth of ten miles to be practically plastic, as shown by M. Tresca's experiments, and that no continuous fissure could occur in such rocks. Estimates of the volumes of ascending lava-columns were given, with a diagram comparing them with a 30-mile thickness of rocks.

Mathematical Society, Thursday, March 11.—Prof. Elliott, F.R.S., President, in the chair.—The President referred to a letter received from the President of the Royal Society with reference to the Victoria Research Fund, which it is proposed to institute in commemoration of Her Majesty's long reign, and commended the fund to the generous consideration of the members. He next spoke briefly on the loss the mathematical world had sustained by the recent death of Prof. Weierstrass.—Mr. Jenkins, Vice-President, having taken the chair, the President communicated a paper, by Mr. J. E. Campbell, on a law of combination of operators bearing on the theory of continuous transformation groups.—On resuming the chair, the President read some notes on symmetric functions, by Mr. W. H. Metzler.—The Senior Secretary briefly communicated a note on some circles connected with a triangle, by Prof. Steggall.—Lieut.-Colonel Cunningham, R.E., mentioned three high primes recently determined by him—$85,280,581$; $234,750,601$; $2,413,941,289$; and gave a sketch of the methods used.

Zoological Society, March 16.—Dr. W. T. Blanford, F.R.S., Vice-President, in the chair.—Mr. Sclater called attention to the two specimens of otters, now living in the Society's Gardens, which had been received from Co. Down, Ireland, last year, and pointed out that they differed in several respects from the common otter.—Mr. A. Smith Woodward gave an account of his recent palæontological tour in Brazil and Argentina, and made remarks on the fossil remains of vertebrated animals that had come under his observation in those countries.—Dr. R. H. Traquair, F.R.S., exhibited and made remarks upon a new specimen of the supposed fossil lamprey (*Palæospondylus gunni*) from the Old Red Sandstone of Caithness, and read a note on its affinities.—A communication was read from Dr. Robert Collett, on a collection of mammals made by Mr. Knut Dahl in North and North-west Australia in 1894-96. The collection contained specimens of thirty four species, two of which—viz. *Pseudochirus dahlii* and *Smithopsis nitela*—proved to be new to science. The former species had been described in the *Zoologischer Anzeiger* for 1895 ; the latter was characterised in the present paper.—Mr. P. L. Sclater, F.R.S., read a paper "On the Distribution of Marine Mammals." The marine area of the globe was divided into six sea-regions, viz. Arctatlantis, Mesatlantis, Indopelagia, Arctirenia, Mesirenia, and Notopelagia, which corresponded to a certain extent with the six land-regions proposed by Mr. Sclater in 1874. The characteristic mammals of each sea-region were pointed out.—Mr. F. E. Beddard, F.R.S., read a paper on a collection of earthworms from South Africa, belonging to the genus *Acanthodrilus*, which had been made in the Cape Colony by Mr. Purcell, of the South African Museum, and forwarded to him by Mr. W. L. Sclater. Examples of nine new species were contained in the collection, which fact was of great interest, as previously only one representative of the genus *Acanthodrilus* had been known to exist in South Africa. Mr. Beddard also described a new genus of earthworms, belonging to the family *Eudrilidæ*, from Lagos, West Africa, under the name of *Iridodrilus*.—Dr. Forsyth Major exhibited a series of skulls and photographs of species of the African bush-pigs (*Potamochærus*), and pointed out the characters of a new species from Nyasaland, which he proposed to call *P. johnstoni*, remarkable for its large size and slender snout. He also showed that the *Nyctichærus hassana* of Heuglin, from Abyssinia, formed a distinct species of *Potamochærus*.

EDINBURGH.

Royal Society, March 1.—Lord Kelvin in the chair.—The Chairman exhibited models illustrating the dynamical theory of hemihedral crystals.—Mr. R. C. Mossman read a second paper on the meteorology of Edinburgh during the past 138 years. There had been no appreciable change in the climatic conditions during that period. The graphs showed nothing approaching to weather cycles. Great snowstorms prevailed during the first quarter of the present century, and during the past twenty-five years there had been an unusually large number of thunderstorms.—Prof. Tait read a paper on the linear and vector function.

Mathematical Society, March 12.—Mr. J. B. Clark, Vice-President, in the chair.—The following papers were read :—Note on combinations, Mr. J. B. Clark.—Note on maxima and minima, Mr. J. Alison.—An application of Sturm's functions-Mr. J. D. Höppner.—A geometrical proof of certain trigono, metrical formulæ, Mr. J. W. Butters.

PARIS.

Academy of Sciences, March 15.—M. A. Chatin in the chair.—The election of M. G. Bonnier in the Section of Botany, in the place of the late M. Trécul, was approved by the President of the Republic.—A new apparatus for the application of spectrum analysis to the recognition of gases, by M. Berthelot. The gas is contained at ordinary atmospheric pressure over mercury in a short glass tube carrying one of the platinum wires, the other terminal being fused into a smaller glass tube, capable of vertical adjustment. The regulation of the striking distance of the spark is of considerable importance in this apparatus, the results obtained in which, although not so delicate as in tubes containing rarefied gas, are still sufficiently good for practical analysis.—On the electric absorption of nitrogen by carbon compounds, by M. Berthelot. A preliminary study showed that much more rapid absorption took place when the induction coil was fitted with a Marcel Deprez high-speed interrupter than when a low-speed vibrator of the Foucault pattern was used. The maximum amount of nitrogen absorbed by a given weight of benzene was 12 per cent. by weight, by carbon bisulphide 11·7 per cent., and by thiophene 8·6 per cent., corresponding to the ratios $3C_6H_6 : N_2$; $3CS_2 : N_2$; and $4C_4H_4S : N_2$. The absorption was most rapid when carbon bisulphide was used, and in presence of an excess of either this or of benzene, the last trace of nitrogen could be completely absorbed.—On the theory of algebraic surfaces from the point of view of geometry of position, and on the integrals of total differentials, by M. Émile Picard.—On a property of asynchronous motors, by M. A. Potier.—Studies on the energy changes in living muscle, by M. A. Chauveau. An inquiry into the relations between the law of conservation of energy and the work done by living muscles. In a comparison of the elastic properties of muscle and india-rubber, it is of the highest importance that the muscle should be living, the elastic properties of muscular tissue separated from the body being quite different from those of the same muscle in the living state. This precaution being observed, there is complete analogy between the elasticity of india-rubber and muscular tissue.—On the relations expressing that the various coefficients considered in thermodynamics should satisfy the law of corresponding states, by M. E. H. Amagat.—On the systems of orthogonal and isothermal surfaces, by M. A. Pellet.—On the method of successive approximations of M. Picard, by M. S. Zaremba.—On the spark discharges and the use of the Hertz oscillator, by M. Swyngedauw. The spark resistance, considered as the resistance of a bad conductor, is regarded by the author as depending upon its length, section, temperature, and the nature of the luminous conductor which constitutes the spark. The consequences of this point of view are different to those deduced by Thomson, who regarded the resistance as constant, and lead to the result that the discharge of a condenser, oscillating for large capacities, becomes continuous for capacities sufficiently small. The Hertz exciter is a condenser of small capacity, and the preceding considerations are applied to it.—On the action of the silent electric discharge upon gases, by M. Émile Villari. Gases which have acquired the property of discharging electrified bodies either by having been sparked, or by having been traversed by the X-rays, lose this power when submitted to the silent discharge of an ozone apparatus. This neutralising power of the ozoniser persists for a certain time after disconnecting it from the coil, the effect being produced by the accumulated charges on the glass.—

Action of high temperatures upon antimony peroxide, by M. H. Baubigny. At a temperature just above the melting-point of gold, antimony peroxide is almost completely decomposed into oxygen and the volatile antimony trioxide.—Action of tannin and some other aromatic derivatives upon some alkaloids and compound ureas, by M. Œchsner de Coninck.—On some derivatives of anethol, by M. Georges Darzens. The unsaturated nature of anethol was shown by the formation of a chlorine derivative by addition. The chlorine was used in carbon tetrachloride solution, a very convenient form of using chlorine in known amounts. This derivative cannot be distilled, as it readily splits off hydrogen chloride, leaving a monochloranethol from which, by addition of chlorine and bromine in carbon tetrachloride solution, the corresponding saturated halogen compounds were prepared.—On the combination of iodine with rice and wheat starch, by M. G. Rouvier.—On the solubility of the red colouring matter of the raisin, and on the sterilisation of the expressed juice of fruit, by M. A. Rosenstiehl.—On the Japanese and Chinese vines acclimatised at Damigny (Orne), and on the composition of the wines which they produce, by M. L. Lindet.—On the composition of the ancient Indian pottery of Venezuela, by M. F. Geay.—Refractory period in the nervous centres, nervous wave, and consequences which result, from the point of view of cerebral dynamics, by MM. André Broca and Charles Richet.—On a new anatomical apparatus observed in the peritoneum, by M. J. J. Andeer.—On some anatomical peculiarities observed in the larva of *Thriaxion Halidayanum*, by M. J. Pantel.—On the relations of *Antennophorus Uhlmanni* (Haller) with *Lasius mixtus* (Nyl), by M. Charles Janet. The *Antennophorus* are parasites living on the *Lasius*, and are nourished by a nutritive fluid exuded by the ants. The parasites always place themselves symmetrically about the body of their host, so that his movements are impeded as little as possible.—On some points in the geology of the environs of Bourganeuf (Creuse), by M. Ph. Glangeaud.—On the use of formaline in the preparation of microscopic specimens, after hardening with osmic acid, by M. Ch. Rousselet.—Synthesis of the elementary forces, by M. Bridou.

DIARY OF SOCIETIES.

THURSDAY, MARCH 25.

ROYAL SOCIETY, at 4.30.—Meeting for Discussion. *Subject*: The Chemical Constitution of the Stars, introduced by J. Norman Lockyer, C.B., F.R.S., with a Communication "On the Chemistry of the Hottest Stars."

ROYAL INSTITUTION, at 3.—The Relation of Geology to History: Prof. W. Boyd Dawkins, F.R.S.

SOCIETY OF ARTS (Imperial Institute), at 8.—The Cultivation and Manufacture of Rhea Fibre: Thomas Barraclough.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—On some Repairs to the South American Company's Cable off Cape Verde, 1893 and 1895: H. Benest. (Continuation of Discussion.)

CHEMICAL SOCIETY, at 8.—The Pasteur Memorial Lecture: Prof. P. F. Frankland, F.R.S.

CAMERA CLUB, at 8.15.—From Mont Blanc to the Matterhorn: Lamond Howie.

FRIDAY, MARCH 26.

ROYAL INSTITUTION, at 9.—Early Man in Scotland: Sir William Turner, F.R.S.

PHYSICAL SOCIETY (Finsbury Technical College), at 5.—Various Exhibitions of Experiments, &c., will be shown by Prof. Thompson and others.

INSTITUTION OF CIVIL ENGINEERS, at 8.—The Re-signalling of the Liverpool Street Terminus of the Great Eastern Railway: W. J. Griffiths.

SATURDAY, MARCH 27.

ROYAL INSTITUTION, at 3.—Electricity and Electrical Vibrations: Lord Rayleigh, F.R.S.

ROYAL BOTANIC SOCIETY, at 4.

ESSEX FIELD CLUB (at Loughton), at 6.30.—Seventeenth Annual Meeting.—Presidential Address: Field Work as Science Training: David Howard.

MONDAY, MARCH 29.

SOCIETY OF ARTS, at 4.30.—Alloys: Prof. W. Chandler Roberts-Austen, C.B., F.R.S.

SANITARY INSTITUTE, at 8.—Ventilation, Warming, and Lighting: Dr. Joseph Priestley.

INSTITUTE OF ACTUARIES, at 7.—Mortality Experience of Assured Lives and Annuitants in France: G. F. Hardy.

CAMERA CLUB, at 8.15.—Snowdon in Winter; Climbing in Dauphiné: Henry Speyer.

TUESDAY, MARCH 30.

ROYAL INSTITUTION, at 3.—Animal Electricity: Prof. A. D. Waller F.R.S.

SOCIETY OF ARTS, at 8.—Lead-work: W. R. Lethaby.

ANTHROPOLOGICAL INSTITUTE, at 8.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Electric Lifts and Cranes: Henry W. Ravenshaw.

ROYAL VICTORIA HALL, at 8.30.—Quicksilver: Dr. H. Forster Morley.

WEDNESDAY, MARCH 31.

SOCIETY OF ARTS, at 8.—Cycling—Historical and Practical: George Lacy Hillier.

CHEMICAL SOCIETY, at 3.—Annua General Meeting.—Ballot for Election of Officers and Council.

THURSDAY, APRIL 1.

ROYAL SOCIETY, at 4.30.—The Croonian Lecture—"The Mammalian Spinal Cord as an Organ of Reflex Action"—will be delivered by Prof. C. S. Sherrington, F.R.S.

ROYAL INSTITUTION, at 3.—The Relation of Geology to History: Prof. W. Boyd Dawkins, F.R.S.

SOCIETY OF ARTS, at 4.30.—A Visit to Russian Central Asia: Michael Francis O'Dwyer.

LINNEAN SOCIETY, at 8.—On the Evolution of Oxygen from Coloured Bacteria: Dr. A. J. Ewart.—On the Germination of Spores of Agaricineæ: Miss Helen Beatrix Potter.

CHEMICAL SOCIETY, at 8.—On the Oxidation of αγ-Dimethyl-α'-Chloropyridine: E. Aston and Prof. J. Norman Collie, F.R.S.—The Composition of Cooked Fish: K. J. Williams.

CAMERA CLUB, at 8.15.—Mountain and West Coast Scenery at Home and Abroad: T. C. Porter.

FRIDAY, APRIL 2.

ROYAL INSTITUTION, at 9.—Metallic Alloys and the Theory of Solution: Charles T. Heycock, F.R.S.

GEOLOGISTS' ASSOCIATION, at 8.—The Physical History of Romney Marsh: George Dowker.—A Collection of Flint Implements from Cookham: Llewellyn Treacher.

SATURDAY, APRIL 3.

ROYAL INSTITUTION, at 3.—Electricity and Electrical Vibrations: Lord Rayleigh, F.R.S.

GEOLOGISTS' ASSOCIATION (Baker Street Station), at 1.37.—Excursion to Chesham and Cowcroft. Director: Upfield Green.

BOOKS AND SERIALS RECEIVED.

BOOKS.—Macmillan's Geography Readers, Book iii. (Macmillan).—The Dahlia: various Writers (Macmillan).—The Popular Religion and Folk-Lore of Northern India: W. Crooke, 2 Vols., new edition (A. Constable).—Dr. Nansen: the Man and his Work: F. Dolman (S.P.C.K.).—The Elements of Electro-Chemistry: Dr. R. Lüpke, translated by M. M. P. Muir (Grevel).—A Manual of Chemistry: Prof. W. A. Tilden (Churchill).—Glaciers of North America: Prof. I. C. Russell (Boston, Mass., Ginn).—The Phase Rule: W. D. Bancroft (Ithaca, New York, *Journal of Physical Chemistry*).—Elementary Text-Book of Physics: Profs. Anthony and Brackett, 8th edition (New York, Wiley; London, Chapman).—Picture Lessons in Natural History (Bacon).—Les Gaz de l'Atmosphère: H. Henriet (Paris, Gauthier Villars).—The Calculus for Engineers and Physicists: Prof. R. H. Smith (Griffin).

SERIALS.—L'Anthropologie, Tome viii. No. 1 (Paris).—American Naturalist, March (Philadelphia).

A DICTIONARY OF BIRDS.

A Dictionary of Birds. By Alfred Newton, assisted by Hans Gadow, with contributions from Richard Lydekker, B.A., F.R.S., Charles S. Roy, M.A., F.R.S., and Robert W. Shufeldt, M.D., late United States Army. Pp. viii + 124 + 1088. (London: Adam and Charles Black, 1893-1896.)

THE publication of the fourth and concluding part of Prof. Newton's "Dictionary of Birds" places ornithologists in possession of a very useful and concise volume in which is to be found a vast amount of varied information concerning recent and fossil birds, and other matter of wider scope bearing upon variation and kindred subjects.

Many of the articles have already appeared in the ninth edition of the "Encyclopædia Britannica," which was commenced in 1875 and finished in 1888. These in the present volume have been collected together, corrected and expanded to date, and to them have been added a number of additional articles, arbitrarily selected, so the author tells us, but with the main object of supplying useful information on subjects concerning which inquiries are often made but not easily answered.

The articles relating to anatomical subjects are from the pen of Dr. Gadow, and we fully endorse Prof. Newton's appreciation of them. They give in a concise form a mass of information on these matters, and will doubtless prove of great value to future workers, not only from their intrinsic merit, but also for the many references to more extended works on the same subjects.

Mr. Lydekker contributes valuable articles on Fossil birds, which give the most recent account of the progress of this profoundly interesting subject. Ornithologists, as a rule, have not neglected to study the morphology of their subject from ancient as well as recent and existing forms, and in urging the necessity of pursuing this course Prof. Newton takes the opportunity, in a footnote (p. 288), of giving an extract from a speech of Huxley's, which it may not be out of place to repeat. "Palæontology," he said, "is simply the biology of the past; and a fossil animal differs only in this regard from a stuffed one, that one has been dead longer than the other, for ages instead of for days."

Prof. Roy's article on Flight sums up the recent theories on the subject, and Dr. Shufeldt's contributions on certain North American forms, concludes the list of matter additional to Prof. Newton's own work, which constitutes the great bulk of the volume, and throngs its pages with very various subjects relating to birds, which have been to him a life-long study from every point of view.

The book is a bulky one (it contains upwards of 1200 pages), yet one cannot help noticing that the exigencies of space must always have been present to the author, obliging him, as he himself declares, to compress his information into the smallest possible compass. That Prof. Newton should succeed in this difficult task no one who knows his accurate and concise methods would doubt, and that he has succeeded must be admitted by every one.

The general arrangement of the articles is, of course, an alphabetical one, but cross references are freely given, which greatly assist in finding information placed under different headings. An initial note must not be lost sight of to the effect that where a word is introduced in small capitals, without apparent necessity, further information concerning it may be sought for under that word in its alphabetical place. The index at the end will also greatly help in finding the subjects; the introduction having an index of names of its own.

Should any article seem to fal short of supplying the most recent information concerning the subject treated of, as is the case in the account of the Birds of Paradise, where no mention is made of the marvellous forms recently brought to light, it must be remembered that it has taken several years to produce the four parts in which the work was issued, and that the sheets were passed for press from the year 1889 onwards.

It is not possible in this short notice to give detailed notes on any of the many valuable articles which abound all through the pages of the book, but interest will no doubt mainly centre on the introduction, which formed article "Ornithology" in the "Encyclopædia Britannica" (published in 1885). This has already been noticed in this journal (NATURE, vol. xxxiii. p. 121), but we may say concerning it that the subject has been since then modified in some respects, and enlarged to bring it up to date. As it stands it is the most comprehensive review of the subject of ornithology extant, and in it will be found a concise summary on most of the important works on ornithology from the earliest times. These are freely criticised, sometimes with favour, sometimes with disfavour, but always, except as some will think in respect to a few recent works, in a judicial spirit.

In this introduction the complex subject of classification is fully treated of, and the various suggested schemes analysed. Prof. Newton, though confirmed in his doubts whether a really valid systematic arrangement of birds has yet been put forth, has hopes that that object may ultimately be attained. We confess that we are not so sanguine, believing that from the nature of the evidence, most of which must long ago have been irretrievably lost, the arguments in favour of many relationships must always be hypothetical, and the resulting classification always liable to modification. Still this impression of ours must not be taken to indicate want of interest on our part in morphological studies in ornithology, for we certainly believe that persistent attempts to elaborate more perfect systems of classification will increase rather than diminish interest in the subject. And this, after all, is of more value than the attainment of any goal.

Prof. Newton tells us in his preface that to his regret he was obliged to omit noticing several interesting subjects bearing upon ornithology, as well as many names of birds beyond those included. He holds out a prospect that these additions may be supplied at some future time. We add our hope that his wishes may be fulfilled, and that they may be taken in hand by the same competent authority.

O. S.

THE PRINCIPLES OF SOCIOLOGY.

The Principles of Sociology. By Herbert Spencer. Vol. iii. Pp. viii + 635. (London: Williams and Norgate, 1896.)

WITH this volume Mr. Spencer has completed his system of "Synthetic Philosophy," the work of thirty-six years. This fact gives a very special interest to his preface, where he tells with dignity and reserve of the disadvantages and disappointments under which his untiring purpose was carried through. Mr. Spencer's comprehensive survey of the sciences in the light of the conception of organic development has abundantly redeemed his promise to his subscribers. But "the first two volumes of the Principles of Sociology have expanded into three, and the third, which if written would now be the fourth, remains unwritten. It was to have treated of Progress." Mr. Spencer has been too much of a pioneer, perhaps, to hope to say the last word of evolutionist science on progress. But if his pleasure in his emancipation, to which he refers as his dominant emotion on the completion of his task, be not too great, we may venture to hope for a further contribution on the subject from the master's pen.

Of the present volume the first part has already seen the light in book form, under the title "Ecclesiastical Institutions." It traces the origin of the religious idea to the apparition of dead ancestors in dreams. "Gods arise by apotheosis." Whatever may be said as to the derivation of certain forms of fetishism and of the animal cults connected with totemism from ancestor worship, it is unlikely that the worship of nature-powers was at its source "but an aberrant form of ghost-worship," as Mr. Spencer holds. But at any rate, in the need to maintain right relations with ghostly powers, there arose the first professions—those of priest and medicine-man. The latter is essentially an exorcist, and his functions are gradually usurped upon by the propitiator of the beneficent spirits of the family, and specially of the chief's family. So that it is from the priest, as he becomes the comparatively leisured and sole repository of knowledge, that the professions draw their origin.

The second section, dealing with Professional Institutions, has already appeared in the shape of review-articles. It finds all those modes of the enrichment and expansion of life, which we call the professions, in germ in the priestly office. Not only teacher, architect, and musician, but actor and lawyer, surgeon and physician, man of science and philosopher spring up in the service and under the shadow of religion. Even where medical appliances were natural, the ideas which accompanied them were supernatural, so that the priest rather than the medicine-man is the source of modern medicine. And notwithstanding much specialisation—witness the Indian rhinoplast—and the empirical training of slave-doctors, the complete emancipation of surgery and medicine is quite modern. It was only the prohibition of clerical shedding of blood that freed the surgeon; it was because their medical duties too much engrossed the time of the clergy, that specialist physicians arose, whom in time a papal bull permitted to marry. Under Henry VIII. a licence to practise in London issued from bishop or dean, "assisted by the faculty." As late as 1858, a medical diploma was granted by his Grace of Canterbury.

To interpret the sacred writings we need grammar. To determine the construction and orientation of altars and shrines, and to fix the seasons of sacrifice, we must have geometry and astronomy. It is the pontiff alone who has the secret of the arch. Hence even the concrete studies of the men of science are priestly; while in Greece alone of the ancient world were these and the abstract speculations of the philosopher emancipated, because "before there was time for an indigenous development of science and philosophy out of priestly culture, there was an intrusion of that science and philosophy which priestly culture had developed elsewhere," and the political incoherence of Greek states prevented the dominance of a hierarchy. Equally ingenious is the treatment of other apparent exceptions, popular music side by side with sacred music in the mediæval world, and the Roman contempt for the slave-actor.

The closing part of the work deals with Industrial Institutions, and is wholly new. An account of the division of labour, which owes nothing to Adam Smith, a history of the origin of exchange, which lays stress on the pre-barter stage, and which draws from the experiences of Cameron a novel illustration of the necessity for the evolution of money, and from the observations of Coote a new example of the qualities found necessary for good money, are followed by a sketch of the development from status to contract, in which the control of family or of chief or, here only incidentally, of priest gives way to guilds originally based on kinship, to free labour and to trades unions, or in which the condition of slavery passes through serfdom to freedom of contract. In this part of Mr. Spencer's work, brilliant though it is, the need that anthropology still has of an adequate method is apparent.

With free labour and its efforts to establish new groupings we pass to the treatment, not altogether convincing from the economist's point of view, of trades unions, co-operation, profit-sharing, and socialism. Of the first, Mr. Spencer is the candid and not hostile critic, though he fears a recrudescence of militant policy, and observes that the guilds, as contrasted with the unions, enforced a standard of work. As regards the rest, Mr. Spencer, feeling sure that all the victories of civilisation have been won by an increase of liberty, is inclined to regard redintegration as a step backward. Though the consideration of the effects of machinery on the labourer, who under the coercion of circumstances as producer "loses heavily—perhaps more heavily than he gains" as consumer, gives pause to Mr. Spencer's optimism, he concludes, as he began "nearly fifty years ago," with the conviction that "the ultimate man will be one whose private requirements coincide with public ones; he will be that manner of man who, in spontaneously fulfilling his own nature, incidentally performs the functions of a social unit, and yet is only enabled so to fulfil his own nature by all others doing the like.'

H. W. B.

OUR BOOK SHELF.

Short Studies in Physical Science. By Vaughan Cornish, M.Sc. Pp. 230. (London: Sampson Low, Marston, and Co., Ltd., 1897.)

New Thoughts on Current Subjects. By the Rev. J. A. Dewe. Pp. 230. (London: Elliot Stock, 1897.)

It may be doubted whether the republication, without additions, of articles and reviews contributed to ephemeral literature serves any useful purpose. Many, if not most, of the articles in Mr. Vaughan Cornish's book are reprints of contributions to *Knowledge* and *The Speaker*; but though they are good examples of what popular scientific articles should be, the fact that they deal to a large extent with current topics, necessarily from the point of view of information available at the time when they were written, and have not been brought up to date, makes their republication undesirable. An article on argon, for instance, written in February 1895 (February 1894, on p. 75, is evidently a misprint), does not contain a satisfactory account of argon as we now know it; and a similar objection may be raised to the articles on helium (written June 1895), on the Röntgen rays (written March 1896), and on Moissan's synthesis of diamonds (written in March 1894). The reprinting of a popular review of a popular book on astronomy is still more open to objection.

The papers included in Mr. Cornish's book deal with subjects in the fields of mineralogy, chemistry and physics. They contain a certain amount of interesting information, and possess the merit of accuracy; so that they may be read with pleasure and profit by the general reader who does not mind being a little behind the scientific times.

The Rev. J. A. Dewe's volume is wider in scope than that of Mr. Cornish; its subjects are social and philosophical as well as scientific. The five essays in the scientific section deal with sea salts and carbonates, the nature of heat, the nature of electricity, stellar and absolute space, and the science and harmony of smell; while among the subjects of the philosophical chapters are free will *versus* heredity and environment, and the dogmatic and scientific accounts of the creation of man. The book has a leaning to metaphysics, but many common experiments are clearly described, and sound conclusions are arrived at from simple arguments. We commend the book especially to men of the author's profession, believing that many of them would acquire breadth of thought by the perusal of it. For ourselves, we are glad to live in the days when a clergyman can calmly discuss facts as to similarity that exist between the physical structure of the human body and that of the monkey, and can say "they lead irresistibly to the conclusion that, as far as the physical part of man is concerned, no exception was made in the laws of the material universe, but that the body of the one slowly developed into the body of the other."

Vorlesungen über Bildung und Spaltung von Doppelsalzen. By Prof. J. H. van 't Hoff. German, by Dr. Theodor Paul. Pp. iv + 95. (Leipzig: Wilhelm Engelmann, 1897.)

The present work is a reproduction of the substance of courses of lectures delivered in Amsterdam and Berlin in the years 1894 to 1896. It will be very welcome to the larger public to which these lectures are thus made accessible. They deal almost exclusively with the researches of the author and his pupils on the formation and decomposition of double salts. The original form of the lectures has not been retained, the subject-matter being treated under three heads. Under the first, the behaviour of a sparingly soluble double salt formed by the union of two binary salts, with or without water of crystallisation, is investigated from the standpoint of the author's theory of dilute solutions and the theory o electrolytic dissociation. The temperatures and pressures at which a double salt can exist, its decomposition by a solvent, and the influence of the presence of one or other of its components on its stability are theoretically investigated.

The second part contains a description of the experimental methods used in the study of the decomposition of double salts, in determining transition temperatures, vapour pressures of the salts and their solutions, solubilities, and other quantities of importance in investigations of this kind. The methods are all original, and this section should be of great service to workers in this field of research. In the third part, the behaviour of bipotassium copper chloride, hexahydrated magnesium potassium sulphate, sodium ammonium and sodium potassium racemates, and the right and left-handed Rochelle salts are minutely described, and shown to be entirely concordant with that theoretically predicted.

These lectures, thus, carry the investigation of the double salts, described in the "Studies in Chemical Dynamics," a step further. In the latter book the temperature at which the complete change of a double salt into its components occurs was fully studied; here the other conditions which affect the existence of double salts are taken into account, and the whole of the region in which such a salt is capable of existence investigated. The book is one with which all who are interested in inorganic and physical chemistry should be acquainted.

Practical Electrical Measurements. By Ellis H. Crapper, A.I.E.E. Pp. xii + 125. (London: Whittaker and Co., 1897.)

The experiments described in this book should be very serviceable in imparting a real knowledge of the fundamental principles of magnetism and electricity. Only by numerous measurements can a student obtain familiarity with measuring instruments and the principles underlying their construction and use. Such work recorded in a systematic and intelligent manner is the best training a student can have to qualify him for the testing-room of electric light and cable stations. The experiments described are almost entirely quantitative, and they include all the usual magnetic and electrical measurements made in physical laboratories. The book thus not only furnishes a course in electrical testing, but may also be profitably used by advanced students in Organised Science Schools and Technical Schools.

Notes of Lessons on Elementary Botany. Prepared to meet the requirements of the Code of the Committee of Council on Education; together with an Appendix, intended as an introduction to a British Flora. By W. Bland. (London and Derby: Bemrose and Sons, Ltd., 1897.)

This little book is not altogether devoid of use; but the author has often sacrificed clearness at the shrine of ambition, in endeavouring to compress about three times too much matter into his pages. As it stands at present, it is fitted to take a place amongst the cram-books, and, like them, is often obscure, or even worse, from the point of view of accuracy. We should pity the child who endeavoured to get on without a large addition of oral help. Many of the figures might well be improved.

Dr. Nansen: the Man and his Work. By Frederick Dolman. Pp. 108. (London: Society for Promoting Christian Knowledge, 1897.)

This is a very simple story of some of Dr. Nansen's characteristics, schemes, and successes. It contains little, if any, new information.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Early Arrival of the Swift.

A FEW minutes before six o'clock in the afternoon of March 26, my brother, Sir Edward Newton, saw, from the cliff near the high lighthouse at Lowestoft, what, at the first glance, looked like a Swallow, flying over the trees in the garden of the house known to many as that occupied more than thirty years ago by the late Dr. Whewell. As the bird turned and gave us a better view of it, we perceived it to be a Swift. Crossing the footbridge and getting to the edge of the Park overlooking the garden, we watched it pass backwards and forwards for about a couple of minutes, when it flew away to the northward, and, though we waited for some little while, it did not reappear. I may add that we were favourably placed as regards light, the sun being behind us. I do not recollect any record of the occurrence of the Swift in England so early as this by some weeks, and it would be interesting to know if the bird should have been observed elsewhere. ALFRED NEWTON.

March 27.

Red Dust of Doubtful Origin.

ON Tuesday morning, March 22, I noticed on the glass of our greenhouses, and on many of the shrubs, a sort of red dust. On making inquiries I found the same thing existed about two miles off, due west. I collected some, and, by the kindness of one of the directors of Messrs. Brunner, Mond, and Co., it was examined in the laboratory connected with their works. To-day I got the report, which is as follows :—

"The dust, under high magnification, shows minute fragments of clayey matter mixed with quartz. Organic matter such as pollen grains are absent. The particles are about 0·0001 millimetres in diameter, many of them less.

"The chemical examination shows clay mixed with a little carbonate of lime and a fair amount of fine sand. The reddish colour is due to oxide of iron."

We are surrounded by grass; the soil is a clayey loam without oxide of iron or quartz.

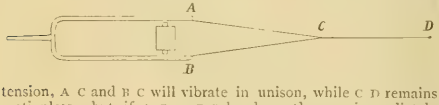
Could any of your readers suggest where the dust can have come from? J. M. YATES.

Davenham, Cheshire.

Experiment on Interference.

I HAVE successfully performed the following experiment on interference :—

To the prongs of an electrically-driven fork are fastened the ends A and B of an elastic string; at the middle point, C, of this string another string, C D, is fastened. D is held in a clip, and the whole stretched. By properly adjusting the lengths and



tension, A C and B C will vibrate in unison, while C D remains motionless; but if A C or B C be damped, C D immediately vibrates.

This is a very pretty experiment when projected, and by flashing the light on it is easily demonstrated that A C and B C are always in opposite phases. JOHN WYLIE.

101 University-street, Belfast, March 8.

The Additional Colouring Matter of "Fucus vesiculosus."

I DO not know whether the following is likely to be of any interest to your readers.

Having prepared a solution of the brown additional colouring matter of the common Bladder wrack, I placed it in the line of a beam of sunlight that had passed through a prism, with the result that the violet indigo and blue rays were entirely intercepted, whilst the yellow orange and red rays were practically unaffected. I repeated this test with vessels that, owing to their flatter form, presented varying quantities of the solution, and in one in which the rays had only to pass through about a quarter of an inch of the liquid the green rays were slightly visible, but neither the blue nor the violet. To make sure that the vessels had nothing to do with the result, I filled them with plain water and passed the beam through them.

Is it justifiable to conclude from this that the action of this additional colouring matter is to protect the chlorophyll from the relative increase of the blue rays, and *not* to heighten the effect, save indirectly, of the others?

Could any of your readers refer me to any papers upon the chemical nature of this additional colouring matter, &c.?

CLARENCE WATERER.

Ingleside, Northdown Road, Margate, March 8.

Chinese Yeast.

IN answer to Mr. C. E. Stromeyer's query in NATURE, March 18, p. 463.

An account of *Levure chinoise*, with details on the manner in which it is prepared, and on the moulds, yeasts, and bacteria it contains, is given by Calmette in the *Annales de l'Inst. Pasteur*, t. vi., 1892, p. 604. A lengthy review of Calmette's paper appeared in *Centralblatt für Bakterologie*, vol. xiii., 1893, p. 273. ITALO GIGLIOLI.

Agricult. Chem. Laboratory, Portici, near Naples.

The Electric Eel.

ON a recent expedition to the N.W. district of British Guiana, I was able to secure a specimen of the electric eel, which I believe to be the largest on record. The fish measured 7 feet 2 inches in length. It was caught with hook and line in a very shallow and unfrequented branch of the Waini River. The skin is now in the local museum. J. J. QUELCH.

British Guiana Museum, March 3.

The Utility of Specific Characters.

I HAVE followed the discussion on this subject with great interest; and though I am at such a distance that my thoughts may come a little late, I wish to call attention to a few points. In NATURE for October 22, 1896, p. 605, mention is made of a discussion on Neo-Lamarckism at the British Association. In opening the discussion, Prof. Lloyd Morgan referred to the importance of noting the bearing of certain cases that may be considered as crucial, or as nearly crucial as any that we are at present able to obtain, on the process by which specific instincts are built up. As illustrating this class of cases, he refers to the drinking instinct in newly-hatched chickens, where the instinctive response begins at the point where the teaching of the parent bird would naturally be inadequate.

The question I wish to raise is, whether such observations as this can do more than justify the conclusion that life-saving instincts are strengthened and established by natural selection. Are they sufficient to show that all permanently inheritable specific characters are wholly due to natural selection, or even that natural selection is always one of the factors by which any and every permanent character has been built up? It seems to me that there are large classes of facts, some of which may be found in almost every species we examine, which throw doubt upon there being any such inseparable connection between natural selection and the inheritance of characters.

The majority of the human species inherit right-handedness. Does this prove that right-handedness is better for the race than left-handedness? The shells of most molluscs are coiled in a way that is called dextral; but some groups of species are as constantly sinistral as most groups are dextral; and of the dextral groups there are certain species that are persistently sinistral; others that are nearly equally divided between dextral and sinistral forms. Is it necessary to believe that for each species that is usually either dextral or sinistral, there is some vital necessity that would exterminate, or even diminish, the species if the character was reversed? A similar class of cases is found amongst the different species of flat-fish. One species persistently lies on the right side, another on the left, and I think it is Mr. Cunningham who has told the readers of NATURE that there are some species in which both forms may occur. In twining plants similar persistence is observed in the direction in which the vine encompasses the support. In each of these classes of cases I am unable to conceive of any advantage gained by the species that would not be equally gained, if the character under discussion was reversed. If the adaptation to the environment of a flat-fish that now lies upon the right side would be equally

good in case all the individuals of the species lay upon the left side, then (if I rightly understand the meaning of the terms), natural selection cannot be the cause of its lying on the right side rather than the left, neither can this character of the species be considered a useful character, though it is persistently inherited.

Standing near me is a flower-pot, in which are several stalks of the common calla (I believe the botanical name is *Richardia æthiopica*) in bloom; and a little inspection shows that each spathe and leaf-bud is twisted in the same way. If the leaf is held with the point up, and the upper surface toward you, the half of the leaf on your left is the part that formed the inside of the leaf-bud, and the margin of the leaf on your right is the part that formed the outside of the leaf-bud This character is quite persistent in the specimens of this species found in this city, though I am told that a leaf twisted in the opposite way sometimes appears; while in the distinct species, popularly called the black calla, I believe the character is reversed. Now, does this persistence prove that the character in question is essential to the welfare of the species? Are we justified in assuming that natural selection is the cause of the persistence of such characteristics? Can any one throw light on the subject that will make it easier to believe that the adaptation of the species would be in the least impaired if all the leaves and spathes were twisted in the reverse way?

The usual method of meeting the natural inference from such cases is based on a double assumption, the first part of which is that natural selection is the only intelligible explanation of the modification of species or the persistence of character that has ever been given, and that, if in any case we abandon this explanation, it is equivalent to abandoning all explanations; the second part of the assumption being that it is simply our ignorance of the facts that prevents us from recognising the life-preserving results that are gained by the characteristic in question. This assumption ignores both the fact that species presenting character of the kind referred to are found on every side, indeed that almost every species that fails to maintain complete symmetry of form is an example, and the fact that Darwin himself pointed out another principle beside natural selection producing persistent characters. This principle of sexual selection he carefully distinguished from natural selection, showing that the results produced by it could never be produced by natural selection, and even maintaining that "It is not surprising that a slightly injurious character should have been thus acquired" ("The Descent of Man," 2nd ed., p. 601).

For my part, I do not think much progress can be made in discovering where natural selection is the chief agent, and where it is not the chief agent, till we have carefully defined what we mean by utility and natural selection, and then adhere to our definitions. In my papers on "Divergent Evolution through Cumulative Segregation" and "Intensive Segregation" (the former published in the *Linnean Society's Journ.—Zoology*, vol. xx.; the latter in the same, vol. xxiii.), I have endeavoured to show that there must be several principles somewhat similar to sexual selection, which I have grouped with it under the names reflexive segregation and reflexive selection. In the former of these papers, pp. 212-214, I have pointed out that "Of freely crossing forms of any species it is only those that are most successful that are perpetuated; while of forms that are neither competing nor crossing, every kind is perpetuated that is not fatally deficient in its adaptations"; and this will be the case whether the forms are held apart by reflexive, or environal segregation.

Let us consider the case of two allied species occupying the same area, and differing from each other in what Dr. Wallace has so appropriately called their recognition marks, and in the segregating sexual and social instincts correlated with these marks. If investigation justifies the belief that an early stage of divergence, due, perhaps, to local segregation, resulted not only in sexual and social segregation, but also in what I have called divergent social selection (or what Dr. Wallace prefers to call selective association), then we are warranted in the belief that this segregative and selective principle was sufficient to perpetuate and intensify the new character, although the section of the species possessing the new character had not migrated into any new environment, and had not been exposed to any change in the old environment, and although it had not gained any new adaptation to the common environment of the two sections, and, therefore, while both sections of the species were equally subject to identical forms of natural selection.

Now, seeing that the individuals of the segregated sections are able to find and keep company with associates, and in the season to pair with suitable mates, as affectually, but no more effectually, than before they were segregated, what shall we say of the usefulness of the distinctive characters that produce the segregation? It is plain that these divergent characters are in constant use; but does that prove that the divergence is a useful divergence? Is it not possible that there should be a difference in use, which is not a useful difference? and if nothing has been gained by the difference either in maintaining the conditions of individual life, or in propagating the species, how can we call it a useful difference? And how can we attribute the divergence to natural selection, seeing natural selection is the superior maintenance and propagation of those better adapted to maintain life under the conditions surrounding the species?

I maintain that this reflexive segregation through the sexual and social instincts of the divergent sections of the species, is the first in a series of divergent characters which may become a great advantage to both sections of the species, by enabling them to become adapted to different kinds of resources, requiring incompatible adaptations; but it cannot be claimed that the usefulness to which this segregative character may attain in the future, or may have already attained, was the cause of the divergence which was steadily perpetuated, being intensified by sexual and social selection, and so completed while as yet this character was of no service to the species. The segregative character is preserved by its segregativeness, though at the time it arises, and for many subsequent generations, it may not be of any advantage to its possessors. In most such cases, I believe, the initial divergence is gained by a local variety, in some measure protected by local segregation; but having gained a character which secures segregation, even when commingled with the other section of the original species, it is no longer liable to be swamped by crossing. It seems to me that such cases are examples of divergence, produced by segregate breeding, brought about by sexual and social segregation, reinforced and strengthened by sexual and social selection, and not by diversity in the action of natural selection.

Another fundamental distinction, that needs to be kept in mind, is that diversity in the action of natural selection on segregated sections of a species may be due to three classes of causes, which are the real causes of the divergence, which results in the production of different species.

(1) Different life-supporting and life-endangering conditions existing in the different districts in which the different sections of the species are distributed.

(2) Different methods of using resources and escaping dangers, adopted by the different sections, though occupying the same district.

(3) Different methods of using resources, and escaping dangers, adopted by the different sections of the species occupying isolated districts, whose resources and dangers are alike.

If the members of the original species are brought under the influence of the first class of causes, it is due to diversity in the environments to which migration introduces them; if under the second class, it is due to diversity in the action of life-preserving habits, while competing with each other; if under the third class, it is due to diversity in this second respect, while not competing with each other.

Now, in some of the cases in the second class and in all those of the third class, it is impossible that the differences should be useful. This is most easily shown as regards the third class; for if in any case a new character attained by one of the sections is an advantage, then the same character would be an advantage for each of the other sections, exposed to the same conditions in other regions, and, therefore, there is no advantage in the difference.

If my thought is correct, some of the differences produced by diversity in the action of the several forms of reflexive segregation and selection, and all those produced by diversity in the action of natural selection, when that diversity is due to different habits that are not necessitated by any difference in the environment, are non-useful differences. Therefore, beside the principle of "correlated variation" referred to by Prof. Lankester (NATURE, vol. liv. pp. 245, 365), we have other explanations of certain kinds of specific characters that are not useful; but the class of characters, of which right-handedness and left-handedness are examples, seem to lie beyond the reach of these explanations, and perhaps beyond the reach of the explanation suggested by Prof. Lankester.

15 Concession, Osaka, Japan. JOHN T. GULICK.

COCCOSPHERES AND RHABDOSPHERES.

THERE have been few more enduring puzzles in natural history than the nature of the Coccoliths, described by the late Mr. Huxley from Captain Dayman's deep-sea soundings in the North Atlantic in H.M.S. *Cyclops* in the summer of 1857. Dr. G. C. Wallich, who was on board H.M.S. *Bulldog*, engaged in a preparatory survey of the route for a telegraph cable about the same date, observed the aggregation of the Coccoliths into spheres, to which he gave the name of Coccospheres. He also pointed out the identity of the Coccoliths with bodies observed in chalk by Mr. Sorby. Mr. Huxley associated them with that unfortunate organism *Bathybius*. "I am led to believe that they are not independent organisms, but that they stand in the same relation to the protoplasm of *Bathybius* as the spicula of Sponges or of *Radiolaria* do to the soft part of those animals" (*Quart. Journ. Micr. Sci.*, vol. viii. N.S. p. 210, 1868). Prof. Haeckel, who received some ooze dredged by Wyville Thomson and Carpenter (*Porcupine* Exped.), put a like interpretation on the phenomena, and published in the *Jenaische Zeitschrift*, vol. v., 1870, a detailed account of the matter with illustrations. *Bathybius* is dead, but one cannot leave it without the reflection that there are few naturalists, the young and expert included, but would have given similar explanation of the appearances. The *Challenger* Expedition next entered the field, and discovered Coccospheres and Rhabdospheres on the surface of the ocean, living free in the water, entangled in the protoplasmic matter of *Foraminifera* and *Radiolaria*, and in the stomachs of *Crustacea* and *Salpæ*. The Rhabdospheres are known only from the tropics, and the Coccospheres, though tropical as well, yet find their finest development in temperate seas. "There is considerable variety both in the form and size of Coccospheres and Rhabdospheres, some varieties having the component parts (Coccoliths and Rhabdoliths) much more compactly united into a sphere than others. The interior of the spheres is perfectly clear when examined fresh from the surface, and becomes coloured brown with iodine solution, but with iodine and sulphuric acid no blue colour was observed. They were never observed to colour with carmine solution. When the calcareous parts are removed by dilute acids, a small gelatinous sphere remains, in the outer layer of which the Coccoliths and Rhabdoliths were embedded" (*Challenger* Reports, "Narrative," vol. i. p. 939). In the Report on the Deep-Sea Deposits, Dr. John Murray treats them as pelagic calcareous algæ (p. 257), and one of us has been criticised with some severity for adopting this view in an "Introduction to the Study of Seaweeds." The Hensen Plankton Expedition, probably through using silk nets of too coarse a texture, failed altogether to find Coccospheres or Rhabdospheres, and Dr. Schütt, the botanist of that expedition ("Pflanzenleben der Hochsee," p. 44), casts doubt on their very existence as organisms, and in any case will have none of them in the vegetable kingdom. Many other naturalists, wise and eminent, British and foreign, have shared, and do share, the opinion of Schütt.

What the Hensen Expedition failed to discover has been effected, however, by quite simple means. A few years ago, Dr. John Murray, while crossing the North Atlantic, obtained the Coccospheres again by simply pumping sea-water through a very fine silk bag. He observed them carefully, and noted their contents to be yellowish, of much the same colour, he now informs us, as the diatoms. While using such a bag last year in diatom work on the *Garland*, it occurred to one of us that Coccospheres and Rhabdospheres might be obtained by this method in the hands of some enterprising mariner. Captain Haultain Milner, of the Royal Mail steamship *Para*, to whom natural history owes many debts, readily consented to put the method to the proof; and, after rehearsing his part in the laboratory of the Botanical Department of the British Museum, sailed last January, equipped with a fine silk bag, tubes with non-acid fixing and preservative fluids, funnels, &c., for the port of Barbados. He was instructed that it would be sufficient to pump for a short time daily with the ordinary deck-hose (intake pipe, three fathoms deep) through the silk bag, and to transfer the residuum to the tubes containing the fixing and preservative fluids. Captain Milner has carried this out, pumping daily in the region agreed upon. It is interesting to observe that Coccospheres abound in the first day's capture (lat. 41°30 N. long. 19°40 W.)—the method succeeded in his hands in the most deadly way—and he subsequently obtained, in the tropical part of his voyage, both forms of Rhabdospheres figured by the *Challenger* Expedition. He got, in fact, not only what the German expedition failed to find any trace of, but all the three forms figured in the *Challenger* Report.

In Fig. 1, *a* and *b*, there are copied from the *Challenger* "Narrative" a Rhabdosphere and a Coccosphere. The Coccosphere figured was obtained from the bottom, and

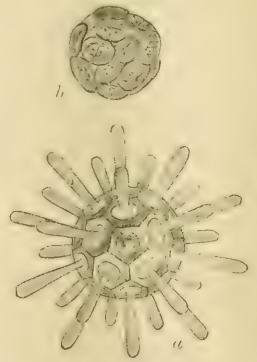


FIG. 1.—*a*, Rhabdosphere × 250; *b*, Coccosphere × 500 (after *Challenger* Report).

shows a disorganised condition. The plates composing the shell of the Rhabdosphere are represented as fitting into each other with geometrical regularity. In the specimens we have seen and been able to examine, not on the heaving deck of a ship at sea, but with the resources and apparatus of modern research, the structure of the shell appears in each case different from that given in the *Challenger* Report. Fig. 2, A, represents a Coccosphere, as we see it, and a very minute and elusive microscopic object it is, under a 1/12th aprochromatic objective. The calcareous scales (or Coccoliths) overlap each other, and constitute not only an excellent defensive armour, but from their arrangement admit of the growth of the organism, which is not thus limited by its calcareous coat, as the diatoms are by their siliceous shells. Each Coccolith is attached to the cell by a button-like projection on its inner surface. A figure nearly resembling ours occurs in *Challenger* Reports, "Deep-Sea Deposits," plate xi. Fig. 3. In the Rhabdosphere, with projecting rods shown in Fig. 2, B, C, the plates (Rhabdoliths) do not fit into each other in the manner figured in the *Challenger* Report, but their bases or bed-plates are embedded on the surface of the cell, each by itself without contact. This may be, on the one hand, a

temporary condition due to turgidity in the specimens observed, or the plates we see may be themselves connected with each other by a finer incrustation. Fig. 2, D, E, represents another Rhabdosphere with trumpet-shaped projections; D, being an optical section, and E a surface view. We have hitherto been unable, partly from the rarity of the objects, to define microscopically the bed-plates to which the trumpets are attached, if such exist. The wall of the cell, probably composed of such plates, presents, in optical section, indications of their existence. At 2 F there is shown the outer end of one of the trumpets.

As to the cell-contents, we have been unable to discover more than the existence of a granular material inside the Coccospheres and Rhabdospheres of both types—a granular material which, under ordinary circumstances, no one would hesitate to call protoplasm. On decalcifying the Coccospheres with very dilute acid, there is left a small gelatinous-looking body which slowly swells up. There is no trace of colouring matter in our

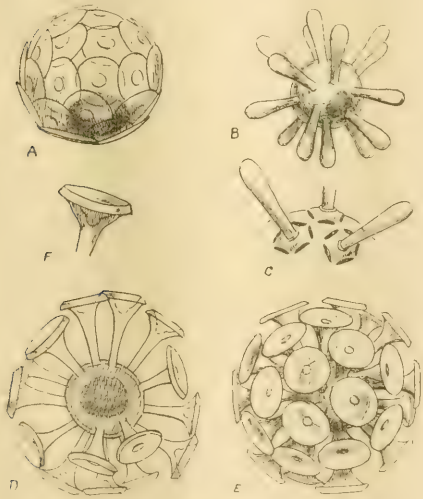

Fig. 2.—A, Coccosphere × 1300; B, Rhabdosphere × 900; C, portion of the same × 1300; D, Rhabdosphere of another type, in optical section, × 1900; E, the same, in surface view, × 1000; F, end of trumpet-shaped projection × 2500.

specimens, and Dr. John Murray, who has seen them, tells us this is frequently the case with specimens examined immediately after capture. They all came from three fathoms, and not from the surface itself. It may be that the living, coloured cell is most abundant at the surface itself, and that our specimens are those which have already begun to sink.

The importance of the part probably played by Coccospheres and Rhabdospheres in the economy of marine life entitles them to a large claim on our interest. They abound in regions of the ocean, out in blue water, and far away from coastal waters, where diatoms and *Peridiniæ* are comparatively scarce; and here their occurrence is in such plenty that their shells on sinking to the bottom constitute nearly 20 per cent. of some deep-sea deposits. Of a like geological history with the diatoms, first appearing in the ancient Cretaceous seas, Coccospheres and Rhabdospheres probably share with them, with the *Peridiniæ* and with the pelagic *Oscillatoriæ*, the *rôle* of food providers to the animal life of the ocean.

George Murray.
V. H. Blackman.

M. ANTOINE THOMSON D'ABBADIE.

THE name of Abbadie has been long and honourably known in the history of science in France. Three brothers of the name have all played a worthy part in geography, in physics, or in ethnography, but the best known is the subject of this short note. The family, which is of ancient descent, appears to have temporarily left their home in the South of France at the time of the political troubles at the end of the last century, and to have settled in Ireland, where, in 1810, Antoine d'Abaddie was born. On the restoration of the Bourbon dynasty, his father returned to France, and it is entirely as a French man of science that Abbadie has won his reputation.

At a time when travelling into and opening-up of the less known and inaccessible parts was not so common as it has proved since, M. d'Abbadie's tastes marked him out as an early explorer. His first journey was made to the Brazils, in 1835, under the auspices of the French Academy; and on his return from South America he started, in 1837, in company with his brother Michel, for Ethiopia, as it was then known. In Abyssinia and in Central Africa the two brothers made a prolonged stay, returning to France in 1848, and their ethnographic and linguistic studies had much interest at the time. The principal results of the voyage were communicated to the French Geographical Society, and were published under the title "Notes sur le haut fleuve Blanc," 1849. The early date at which this exploration was made is of equal importance with the results gathered. If the accuracy of some of these results has been questioned, they at least indicated the necessity for further investigation. The journeys of Richardson and Barth were some years later. Burton and Speke began their travels in 1853. Livingstone returned to this country with his first results in 1856; so that M. d'Abbadie is certainly entitled to be remembered as a pioneer in African research.

Though M. d'Abbadie gave much attention to linguistic work, he applied himself to astronomical pursuits with some eagerness. In 1837, he visited Norway, with the view of observing the total solar eclipse of that year. The point to which he directed his attention was the examination of the light of the solar prominences for the detection of polarisation. With the view of still further satisfying himself on this point, he took advantage of the eclipse of 1860 to go to Spain, where, accompanied by M. Petit, of the Toulouse Observatory, he made some further observations at Briviesca. Observing with a quartz plate and double-image prism of small angle of separation, no trace of polarisation was detected. The account is given in the *Ast. Nach.*, No. 1290. Later, in 1882, and notwithstanding his advanced age, M. d'Abbadie took charge of one of the French stations selected for the observation of the transit of Venus. The position occupied was at Port au Prince, in Saint Domingo, a station well adapted for observing the effects of both retarded ingress and accelerated egress. The observations were successful.

M. d'Abbadie was elected Chevalier of the Legion of Honour in 1850, and became Member of the Academy in 1867. He has occupied a seat at the Board of Longitude since 1878. He was elected a Fellow of the Royal Astronomical Society so recently as 1895, his interest in astronomy having probably quickened in the later years of his life. This is shown by the disposition of his property, which is handed over to the Academy of Sciences on the condition that the Society publishes a catalogue of half a million of stars within the next fifty years.

MR. W. W. RUNDELL.

A LARGE circle connected with the British Mercantile Marine, besides many others interested in magnetic science, will regret to learn that W. W. Rundell, so long associated with Liverpool and its nautical affairs, died a few weeks ago at the advanced age of eighty-one.

We first hear of Rundell in 1845, when he became Secretary of the Cornwall Polytechnic Society, a post which he held until 1855, when he was appointed Secretary of the Liverpool Compass Committee.

It will be remembered that this Committee sat during the years 1855–57, and by 1860 had made three reports to the Board of Trade on the magnetism of a majority of the iron ships leaving the port of Liverpool, the necessary compensations to be made for the resulting deviations of ship's compasses, and the proper equipment and placing of such compasses. This was a work of the highest importance at a time when iron ships were rapidly increasing in numbers, and much danger existed in their navigation from the ignorance which prevailed on the subject.

To Rundell was entrusted the details of the experimental investigations, and the keeping the necessary records of proceedings, an onerous post which he occupied with great zeal and marked perception in reducing and coordinating a mass of results, often of an apparently contradictory nature.

In the spring of 1857 the Liverpool Compass Committee was dissolved, and Rundell was appointed Secretary of the Underwriters' Association of Liverpool; but for the succeeding three and a half years he worked during his leisure hours at the preparation of the valuable third Report of the Liverpool Compass Committee, and this altogether as an honorary task.

Although in many questions relating to the magnetism of ships he was ready to work cordially with Smith and Evans, who were then carrying on an important work connected with the magnetism of ships in the Royal Navy, Rundell had one important difference of opinion with them—as regards the mechanical correction of compasses.

Smith and Evans objected strongly to compensating the standard compasses of ships by magnets and soft iron, advocating reliance upon deviation tables for correcting the compass courses steered. Rundell, supported by his friend Towson, insisted on the complete compensation of compass errors, so strongly advocated by Airy the inventor of the methods of doing so. The Mercantile Navy followed him, and he has lived to see the Royal Navy more bent on rigorous compensation than the Mercantile.

In 1862 he contributed an excellent paper on compass equipment in iron ships to the Institution of Naval Architects, followed by another on the same subject in 1866. This latter paper contained a vigorous protest against Government supervision of merchant vessels as regards their compasses, and especially to placing the regulation of their equipment under the control of the Admiralty Compass Department, as proposed by the Royal Society to the Board of Trade, but declined by the Board.

Rundell, however, did not content himself with a protest, but made some excellent propositions, which for the most part have been adopted by the Board of Trade.

Zealous and painstaking in whatever he undertook, firm in any position which his well-balanced mind caused him to take up, Rundell was of a kindly disposition and surrounded by friends, many of whom he has survived. He has left an indelible mark on the service to the benefit of which so many years of his life were devoted.

E. W. C.

NOTES

ON Monday last, Lord Lister's professional brethren gave a visible sign of their high regard for him, and their appreciation of his work, by presenting his portrait, executed by Mr. W. W. Ouless, R.A., to the Royal College of Surgeons. In making the presentation on behalf of the subscribers, Mr. Davies Colley remarked that before long he hoped that those thousands who owed life and health to Lord Lister's discoveries would show their gratitude by founding some institution, or raising some great monument in his honour. There was, however, a special fitness in having a portrait painted of one who had done so much to advance the science of surgery, and placing the picture side by side with the portraits of John Hunter, Astley Cooper, and the other great surgeons who had done similar work. Sir William MacCormac, President of the College, in accepting the portrait, pointed out that a revelation in surgery, one of the most beneficent which has happened in our time, has been the result of Lister's patient investigation. It was not necessary to enter into details as to the incalculable benefit which has flowed from the application of antiseptic principles to surgery. Every surgeon must feel a debt of personal gratitude to the man who enabled operations in surgery to be practised with a safety and in a manner heretofore unknown. In the course of a brief reply, Lord Lister is reported by the *Times* to have said: "It would be affectation to deny that I feel this occasion to be one of extreme gratification. I cannot but be conscious that it is a very high personal honour and a remarkable token of esteem and kindly feeling on the part of my colleagues in the noble profession of surgery. But I confess I feel it still more gratifying as a remarkable indication of the general acceptance of the principles which I have for so long a time striven to establish and to promulgate. I am glad this meeting cannot be regarded in any sense as a mere meeting of congratulation on the distinction, great as I am bound to say I feel it to be, which it has pleased Her Majesty to confer upon me, because this project of a portrait was set going before that honour was thought of. This circumstance makes the occasion still more markedly a tribute to the truth and importance of antiseptic principles. Those principles are now more and more recognised throughout our profession, and with increasing benefit to mankind. I was reading only to-day a pamphlet which was sent to me by the author, Dr. Coaley, of New York. In it it was stated that in 360 antiseptic operations for the radical cure of hernia, only one death occurred, not caused apparently by the operation, but by the anæsthetic ether given to a child with weak lungs. An achievement like that is enough to cause gladness in the heart of any man who loves his fellow-men. And yet I cannot help remarking that such results could not have been obtained by the mere recognition of the truth or importance of antiseptic principles. Such success implied that the operator was not only convinced of the truth of those principles, but also that he vigilantly maintained throughout his operations that earnest care which is necessary to prevent those principles from being contravened."

PROF. HERMANN MUNK has been elected president of the Berlin Physiological Society, in succession to the late Prof. Du Bois Reymond.

THE Swedish Academy of Agriculture of Stockholm has awarded its gold medal to Prof. J. Eriksson, for his researches on the rust of cereals.

A COMMITTEE has been formed to collect international subscriptions for the erection of a memorial to the late Prof. Galileo Ferraris in the Royal Industrial Museum, Turin.

The Prussian Academy of Sciences has elected Prof. Ernst Ehlers, Professor of Zoology in Göttingen University, and Prof. G. Darboux, the distinguished French mathematician, to be corresponding members.

The American Academy of Arts and Sciences have elected as foreign members: Prof. Ludwig Boltzmann, professor of theoretical physics at Vienna; Prof. W. Pfeffer, professor of botany at Leipzig; and Dr. W. Dörpfeld, secretary of the German Imperial Archæological Institute at Athens.

The Naturalists' Association of Danzig has offered a prize for the best treatise on the origin and spread of fungus epidemics among insects which are injurious to the forests in West Prussia, and for the best means of applying them to the destruction of the insects. The papers are to be sent in by December 31, 1898.

At the recent annual meeting of the Sanitary Institute, H.R.H. the Duke of Cambridge, K.G., was re-elected President. Prof. W. H. Corfield and Mr. Thomas Salt were elected new Vice-Presidents, to fill the vacancies caused by the death of Sir George M. Humphry and Sir J. Russell Reynolds.

Mr. A. A. C. Swinton will give a paper on recent investigations in connection with X-rays, at the Camera Club, on April 12, when he will show a number of experiments illustrative of the properties of kathode and X-rays, and will exhibit a new and improved form of Crookes' tube he has designed for practical work. This tube is capable of easy adjustment, so as to give X-rays of any desired penetrative value.

Dr. Nansen was enthusiastically received at the Paris Geographical Society on Friday last, when he gave an account of his polar explorations. M. Rambaud, Minister of Education, presided, and, before the lecture, invested Dr. Nansen with the insignia of Commander of the Legion of Honour. Dr. Nansen also received the gold medal of the Society, and a medal from the Municipality of Paris.

Persistent efforts are being made in France by the Commission officielle pour la division décimale du temps et de la circonférence, to secure the adhesion of scientific societies to the division of the hours of the day into 100 parts, each to be again subdivided into 100 parts. This method of dividing time has evident advantages, but it also has its inconveniences; for instance, the C.G.S. unit of time, officially adopted at the International Congress of Electricians in 1881, would have to be discarded. To obtain an opinion upon the proposed decimal division of time, the Société Française de Physique has sent out a circular to its members, and has appointed a committee to consider the replies received, and to advise therefrom as to the action the Society should take.

The United States Government in 1895 appointed a "Deep Water-Ways Commission," for the purpose of making a preliminary investigation of the possibility of opening a deep waterway from the great lakes to the sea. This Commission has now reported that it is quite practicable to construct such canals as will be adequate to any scale of navigation that may be required between the great lakes and the sea; and recommend that the depth of any water-ways so constructed, should not be less than 20 feet. They also find that the most eligible route, starting from the heads of Lake Michigan and Superior, is through the several lakes and the proposed Niagara ship canal to Lake Ontario; and that the Canadian sea-board may be reached from Lake Ontario by way of the St. Lawrence; and the American sea-board by way of the St. Lawrence, and Lake Champlain, and the Hudson river; or by way of the Oswego-Oneida, Mohawk valley, and the Hudson river. They recommend that the Niagara ship canal should be first commenced, and that the other works required should be pushed on with as quickly as the projects can be matured; and that further surveys be undertaken, estimates of the cost prepared, and a systematic measurement of the outflow of the lakes undertaken. The cost of these investigations is estimated at about 126,000*l.*, and it will require two or three years to complete them. The President, in sending the report to Congress, advised that provision be made for carrying on the work of preliminary examination. The Canadian Government has also appointed a Commission to look into the question, and a joint session of the two Commissions was held at Detroit in last year.

The advantages of the absolute system of electric units have led Prof. Leonhard Weber to propose a similar system of units for photometric purposes. In the *Elektrotechnische Zeitschrift*, Prof. Weber points out that in photometry we have to deal with six different quantities, viz. intensity of light, flux of light, quantity of light, illumination, brightness and time-integral of illumination. Taking a *candle* as the unit of intensity, he shows how all these quantities can be expressed in terms of the candle, centimetre and second; or the candle, metre and hour. The objection to this proposed system, to our mind, is the adoption of a candle as one of the fundamental units; in order to obtain a perfectly absolute system of units, quantity of light should be measured in terms of the energy radiated, and the unit of intensity would then be that of a source from which the amount of energy radiating per unit solid angle per second was one erg. This would reduce all photometric quantities to the C.G.S. system of units.

Prof. A. Gray writes, with reference to his article in Nature of last week, that Lord Kelvin has called his attention to the fact that the account of Lord Kelvin's telephone-line and the establishment of telephony in Glasgow, is not quite exact. The telephone-line to Lord Kelvin's instrument-makers' was only one, and no doubt an early one, of a number of separate or independent lines which were established in Glasgow, and in other places, soon after the introduction of the telephone to this country by Prof. Graham Bell.

Messrs. Allen and Chapman, of New York, have just issued (extracted from the *Bulletin* of the American Museum of Natural History) an article on the "Mammals of Yucatan," where Mr. Chapman has lately made a brief stay. This dry and sparsely-wooded country has by no means a rich mammal-fauna; but during his short visit Mr. Chapman was able to secure examples of fifteen species, amongst which two or three rodents are described as new.

Messrs. Allen and Chapman also send us (extracted from the same periodical) an article on a collection of mammals made by Mr. Chapman, in Trinidad, during his trip to that island in 1894. The total number of mammals now recognised by the authors as found in Trinidad is about sixty-five species, of which forty are represented in the present collection. Of these a bat and three small rodents are referred to new species. Unfortunately, under the guise of priority, the American zoologists introduce so many new names into their recent works, that it is, in many cases, very difficult for their old-fashioned brethren of Europe to understand what they mean by them.

The latest contribution to the interesting subject of the primitive wild cattle of Europe is a short illustrated article, by Dr. A. Nehring, on Anton Wied's "Muscovia," a famous publication of the sixteenth century, in which a very incorrect figure of the urus was depicted. In the German edition of this work, by Herberstain, published in Vienna in 1557, characteristic figures are given of the European bison or wisent (*Bison europæus*) and of the urus (*Bos primigenius*); but the best illustration of the latter known to Prof. Nehring is that of a clever unknown artist of the first quarter of the sixteenth century, which was copied in

Griffiths' "Animal Kingdom," London, 1827 (vol. iv. p. 411). The above-mentioned illustrations are reproduced in Dr. Nehring's paper in *Globus*, Bd. lxxi. p. 85.

THE *Annalen der Hydrographie und maritimen Meteorologie* for February, issued by the Deutsche Seewarte, contains a discussion of the storms of the western part of the South Atlantic Ocean, by E. Knipping, based upon the observations of 252 storms, mostly reported in the logs of German vessels. In higher latitudes than 30° S. only storms of hurricane force (11 and 12 of the Beaufort wind-scale), and in latitudes below 30° S. all storms of force 8 are included. The results show that no storm occurred to the east of 27° W. long. and north of 29° S. lat. The yearly distribution westward of 25° W. long. is very marked; for one storm in summer there are five in winter. The months of November to March are free from storms below 30° S. lat.; stormy trade-winds occur as far as 28° S., but only from April to October, and mostly with high and somewhat steady air-pressure. From 25° to 40° S. storms occur more frequently within a distance of 500 miles from the coast than beyond that area. In north-easterly storms the mean change of wind direction over the whole district amounts to 8 or 10 points of the compass in a left-hand direction, while in south-westerly storms there is little or no change of direction. In north-west storms below 30° S. there is little or no change, while above that latitude it amounts to 4 or 6 points to the left. The mean duration increases with the latitude; from 20° to 30° S. the north-easterly storms last twice as long, and from 30° to 40° S. only half as long as storms from other directions. The greatest force of the storms generally occurs with a rising barometer, *i.e. after* the time of the lowest reading, except in the case of easterly storms, when it occurs as frequently with a falling as with a rising barometer.

IN May 1895, Mr. W. E. Wilson read a preliminary paper before the Royal Society, in which he described the apparatus and results of his investigation of the effect of pressure in the surrounding gas on the temperature of the crater of an electric arc. It may be remembered that the chief aim of the research was to determine, if possible, whether the temperature of the crater in the positive carbon varies when the pressure in the surrounding gas is changed. In a more recent investigation (*Astrophysical Journal*, vol. v. No. 2, p. 101), Messrs. Wilson and Fitzgerald give the results of further work on these points. These may be briefly summed up as follows:—That more evidence than they have obtained must be procured before they are able to affirm that either the temperature of the crater of the arc is raised or lowered by pressure. They, however, made some very concordant observations, which showed that the temperature was lowered with pressure, and in which at the time they could see no evidence of absorption by fog; but then, at other times, there were undoubted cases of absorption. "We certainly got no evidence that there is an appreciable increase of temperature." The best observations, the authors further say, "were made with variations of pressure from 15 up to 100 pounds per square inch, and there seems very little evidence of much change of radiation with this change of from 1 up to between 6 and 7 atmospheres."

REMARKING on these interesting researches of Mr. Wilson, M. Guillaume writes that they seem to have shown that the temperature of the crater in the positive carbon is not limited to the boiling of carbon. Referring to the early researches of MM. Humann and Hogarth (*Pro. R.S.*, vol. xxx. p. 178), and taking into account the recent investigation of M. P. Villard (*Journal de Physique*, vol. v. p. 453, 1896), M. Guillaume presented to the Physical Society of France, on July 20, 1896, the essence of a theory of the arc under pressure, based on the "dissolution du carbone dans le gaz ambiant." This idea seems to be in perfect harmony with the experiences of Violle, Wilson and Villard; and the fact observed by Wilson and Fitzgerald, that they "found that whenever the pressure was suddenly reduced there was a fog formed in the box, which cut off the light enormously," speaks well, as M. Guillaume says, for the accuracy of his theory. The temperature of carbon seems to be limited by the rapidity of the "dissolution" in the surrounding atmosphere, and ought to decrease when the pressure increases.

MR. ASA S. KINNEY has made a number of experiments for the purpose of obtaining some definite knowledge as to the influence of electricity upon plants, and his investigation forms the subject of *Bulletin* No. 43 of the Hatch Experiment Station of the Massachusetts College. The current employed was in some cases produced by four Leclanché cells, and in others by a Samson cell giving an electro-motive force of two and eighty-eight hundredth volts. An induction coil was used, so as to obtain a large variation in electro-motive force. The stimulation thus provided was applied to moistened seeds in glass jars, and upon filter papers. So far as the experiments go, they show that electricity exerts an appreciable influence upon the germination of seeds, the application of certain strengths of current to seeds for short periods of time apparently accelerating the processes of germination. As a result of experiment, it was found that at the end of twenty-four hours over 30 per cent. more seeds were germinated in the treated lots than in the normal. The range in the strength of current which accelerated germination seems to be exceedingly limited. The minimum strength of current, which just perceptibly accelerated germination when an interrupted induced current was used, probably represented considerably less than one volt. The optimum strength of current, which showed the maximum growth of radicles and hypocotyls, was equal to about three volts where an interrupted induced current was used. The maximum current which the seed germ could withstand without being destroyed was not ascertained, but it probably represents a comparatively high voltage. Arrangements were made to send an hourly current through the germinating seeds and growing plants, and it was found that the electricity did not lose its effect, but acted as a constant stimulation to their growth and development. The seeds used were of white mustard, red clover, rape, and barley, and measurements were made of about three thousand roots, and nearly one thousand stems.

DR. W. A. SOGA and Mr. H. Percy Browne have recently made some very important tests of the value of a certain fungus for destroying locusts by infecting them with it. The fungus is prepared by Dr. Edington, of the Bacteriological Institute, Grahamstown, and, judging from the experiments described in the Cape *Agricultural Journal*, great benefits may be expected to be derived by using it to infect locust swarms. A few locusts are caught and treated with the fungus; they are then set free, and inoculate other members of the swarm, with the result that in a few days the locusts die in large numbers.

THE Summary Report for 1896 of the Geological Survey of Canada affords very interesting reading. The year has been marked by a notable development in mining, and by a remarkable discovery of corundum in a pegmatite in Ontario. The deep boring at Athabasca, described in the two last reports, has had to be abandoned after nearly 2000 feet of Cretaceous rocks had been sunk through, without the petroleum-beds being reached: the boring is not, however, a failure, as the knowledge gained will probably enable a successful boring to be made elsewhere. Mr. Chalmers, in Quebec province, finds evidence of extensive post-tertiary earth-movements in the many narrow lakes and uplifted shore-lines. In Nova Scotia, Prof. Bailey has successfully delimited the Devonian and Silurian formations, but has not been so fortunate with the supposed Cambrian (but

unfossiliferous) rocks. Messrs. Barlow and Adams have carried modern methods and ideas into a survey of the classical Laurentian territory, but their work deserves more extensive notice than can now be given. We have also received the mineral statistics for 1895 from the same Survey.

BULLETIN 2, vol. ii. of the Geographical Club of Philadelphia, contains an account of a trip to Manikaland, by Mr. J. E. Farnum. The route followed the course of the Urema, which flows from Sungue Lake and joins the Pungue, about 45 miles above Fontisvilla, the starting-point of the railway to Salisbury. The country here, northwards to the Zambesi, and 150 miles south to the Bosi River, is perfectly flat, with scattered depressions, forming swamps during the greater part of the year. The soil is black sandy loam, supporting long grass, sometimes fifteen feet high, and a few palm trees; and in the drier parts dense tropical forest. Gutta-percha is obtained from one of the few creepers, and sold in small lumps to the Portuguese traders. The people are evidently degenerate, having few or no ceremonies or traditions of any kind.

WE have received Parts 2 and 3 of vol. xx. of the *Transactions and Proceedings* of the Botanical Society of Edinburgh, which give evidence of the continued activity of scientific research in the northern capital. Mr. R. S. McDougall has an elaborate paper on the poisonous properties of some Leguminous plants, especially of *Lathyrus sativus*. Mr. T. Cuthbert Day contributes an article on the germination of barley with restricted moisture, accompanied by a number of tables. In a valuable paper on the pigments of plants, by Miss M. J. Newbigin, the authoress attempts a classification of the colouring matter of flowers, and offers some suggestions with regard to their purpose in the physiology of the plant. But we would venture to suggest to the compilers of this and of some other journals, that the reviewer has scarcely a fair chance of appreciating their value when, as in the present instance, there is no kind of index or table of contents to each separate part, and even no descriptive headline to the pages.

A SERIES of articles upon the botanic gardens of the world is in course of appearance in the *Pharmaceutical Journal*. In the current number of the journal (March 27) an interesting article on the Royal Gardens at Kew is continued.

THE *Comptes rendus* of the meetings of the Congrès international des Pêches Maritimes, held at Sables-d'Olonné in September last, have just been published, as a volume of four hundred pages, by the Institut international de Bibliographie scientifique, Paris.

THE following are the arrangements for lectures on Tuesday evenings, at 8.30, at the Royal Victoria Hall, Waterloo-road S.E.:—April 6, Rev. George Henslow, on "The Movements of Plants"; April 13, Mr. F. W. Rudler, on "Modes of Mountain Making"; April 20, Prof. B. J. Malden, on "Africa up to date"; April 27, Dr. W. B. Benham, on "The Life of an Egg."

THE first number of the *Aeronautical Journal* has made its appearance. It is the organ of the Aeronautical Society of Great Britain, which is now undergoing resuscitation. Interest in flying and flying-machines, and atmospheric exploration, has lately received such a decided impetus, that the Society should have no difficulty in increasing its membership, or in obtaining topics for consideration.

A NEW quarterly magazine, devoted to subjects of general and permanent interest concerning "East Asia," which is the title it will bear, will appear in June. Articles will be contributed to the magazine on the past history and present condition of Eastern Asia; the buildings, institutions, and customs; the races of men; the plants and animals; the religion and literature; and on the voyages and adventures of old travellers. *East Asia* will be conducted by Mr. Henry Faulds, Fenton, Stoke-on-Trent, and published by Messrs. Marshall, Russell, and Co.

WE notice with satisfaction that *The Photogram* is endeavouring to make photographers into investigators, by presenting some of the results obtained by the use of photography. The applications of photography in the technology of explosives, in civil engineering, and in entomology, were dealt with in the first three numbers of this year, and the April number contains several fine illustrations of the effects produced on the surface and within the mass of liquid, when a liquid jet strikes the surface.

THE Association for the Harmonious Development of Faculties, an object which has the sympathy of all, if not the support, has followed up the publication of a sensible little pamphlet on "Common-sense Ethics" by another, on "Confucius: his life and his doctrine" (Williams and Norgate). The great Chinese philosopher used to send away his disciples who did not show sufficient ardour for study, or such as were not sufficiently intelligent to understand him. "When," said he, "I have shown a pupil one corner of the subject, and he is unable to discover the other three, I do not repeat my lesson." Confucius evidently understood the value of self-help.

THE Cheltenham College Natural History Society has issued a report of the proceedings during the year 1896. We welcome this, as we do all similar evidence of interest in science, and of observations made in the true spirit of inquiry. The sections of archæology, botany, entomology, geology, ornithology, and photography have all assisted in increasing the knowledge of the facts of nature, and the lectures, two of which, on "Argon and Helium" and "Cheltenham in the Old Days," appear in the report, have given the members of the Society something to think about. Too great encouragement cannot be given to such natural history societies as that at Cheltenham and other schools.

IF there is any book to which the word indispensable can be applied without being a figure of speech, it is the "Statesman's Year-Book" (Macmillan), the thirty-fourth annual publication of which we are pleased to announce. Under the editorship of Dr. J. Scott Keltie, assisted by Mr. J. P. A. Renwick, the book has become a unique statistical and historical annual of the states of the world. The present issue is a volume of 1167 pages, three hundred of which are devoted to the British Empire, and the remainder to foreign countries. To indicate the political changes which have taken place during the sixty years of Her Majesty's reign, eight pairs of coloured maps have been inserted, exhibiting, side by side, the political divisions of the continents in 1837 and 1897. It need hardly be said that the two maps of Africa, compared in this way, present a very striking difference. Other new features have been introduced, and the whole work stands out as a trustworthy and never-failing book of reference on political and commercial geography.

THE South London Entomological and Natural History Society has for many years cultivated the spirit of scientific observation, and added to the number of workers in the extensive field of natural history. The proceedings of the Society for the year 1896 testify to a condition of well-directed activity and sustained interest in the ways and works of nature. There are many noteworthy papers in the report, and they are made valuable by the fact that they record the results of direct observation. We note with satisfaction that Mr. Robert Adkin, in the

course of his presidential address, points out how entomologists may assist in elucidating many problems of biology. He rightly remarks that, "Without entering very far into the philosophical phase of his subject, every practical entomologist has it in his power to contribute something towards solving one or the other of the problems connected with variation, heredity, and the general laws operating in the production of species. He is already expert at rearing insects from the egg; let him continue to do this, but let him conduct his rearing operations on experimental lines. . . . A useful course of experimental work would be to endeavour to develop some particular varietal tendency exhibited by a species."

THE spring announcements of the Cambridge University Press include:—The Collected Mathematical Papers of the late Arthur Cayley, F.R.S., to be completed in thirteen volumes, vol. xii.; The Scientific Papers of John Couch Adams, F.R.S., vol. ii., edited by Dr. W. G. Adams and R. A. Sampson; The Foundations of Geometry, by the Hon. B. Russell; A Treatise on Abel's Theorem, by H. F. Baker; The Theory of Groups of a Finite Order, by W. Burnside, F.R.S.; A Treatise on Universal Algebra, with some applications, by A. N. Whitehead. Vol. i. contains the General Principles of Algebraic Symbolism: The Algebra of Symbolic Logic: The Calculus of Extension (*i.e.* the Algebra of Graffmann's Ausdehnungslehre), with applications to Projective Geometry, to Non-Euclidean Geometry, and to Mathematical Physics; A Treatise on Octonions: a development of Clifford's Bi-Quaternions, by Prof. Alexander McAulay; A Treatise on Spherical Astronomy, by Prof. Sir Robert S. Ball, F.R.S.; A Treatise on Geometrical Optics, by R. A. Herman; An Elementary Course of Infinitesimal Calculus, for the use of Students of Physics and Engineering, by Prof. Horace Lamb, F.R.S.; Theoretical Mechanics: an introductory Treatise on the Principles of Dynamics, with numerous applications and examples, by A. E. H. Love, F.R.S.; The Works of Archimedes, edited in modern notation, with introductory chapters, by Dr. T. L. Heath; Handbook to the Geology of Cambridgeshire, by F. R. Cowper Reed. Cambridge Natural Science Manuals.—(Biological Series) Fossil Plants: a Manual for Students of Botany and Geology, by A. C. Seward; The Vertebrate Skeleton, by S. H. Reynolds; Vertebrate Palæontology, by A. S. Woodward; (Physical Series) Electricity and Magnetism, by R. T. Glazebrook, F.R.S.; Sound, by J. W. Capstick; (Cambridge Geographical Series) A History of Ancient Geography, by the Rev. H. F. Tozer, with ten maps.

THE additions to the Zoological Society's Gardens during the past week include a Chacma Baboon (*Cynocephalus porcarius*, ♂), a Levaillant's Cynictis (*Cynictis penicillata*), a Black-backed Jackal (*Canis mesomelas*) from South Africa, presented by Mr. J. E. Matcham; a Cheetah (*Cynælurus jubatus*) from Africa, presented by Colonel W. H. Wylde; a White-bellied Pangolin (*Manis tricuspis*) from Lagos, presented by Mr. F. W. Marshall; an Alexandrine Parrakeet (*Palæornis alexandri*, ♂) from India, presented by Mrs. Randall; a Severe Macaw (*Ara severa*) from South America, presented by Mrs. J. Keser; three Indian Pigmy Geese (*Nettopus coromandelianus*, ♂ ♂ ♀) from India, presented by Mr. Frank Finn; a Tesselated Snake (*Tropidonotus tesselatus*) from South Europe, presented by Mr. W. R. Temple; a Natal Python (*Python sebæ*, var.) from South Africa, presented by Mr. Luscombe Searelle; three Purplish Death-Adders (*Pseudechis porphyriacus*), a Shielded Death-Adder (*Notechis scutatus*), three Australian Banded Snakes (*Diemenia nuchalis*), an Occipital Elaps (*Furina occipitalis*) from Australia, deposited; a Maximilian's Aracari (*Pteroglossus wiedi*) from Brazil; two Rosy-faced Love-Birds (*Agapornis roseicollis*) from South Africa, purchased; two Collared Fruit Bats (*Cynonycteris collaris*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

THE PLANET MARS.—Prof. Schiaparelli has just published an account of his observations of Mars made during the years 1883-84. These observations are contained in the publication of the *Reale Accademia dei Lincei*, 1895-96, and are accompanied by a new chart of the surface-markings and eight diagrams of the planet's disc. Of the thirty-one canals seen to develop in 1881 and 1882, only eighteen have been observed again at this opposition, while seven new ones have been noted. In the polar gap a large dark rift was seen, apparently separating the snow into two unequal portions. An examination of the chart with that published by Lowell will be found to give many interesting points of difference. In the March number of the *Bulletin de la Société Astronomique de France* there will be found a brief account of these observations, with reproductions of the plates in Schiaparelli's original memoir. There are added a series of drawings of the planet observations, made from the Observatory of Juvisy, at the opposition in December last.

Some interesting observations, made of Mars last year, are contributed to the current number of the *Astronomischen Nachrichten* (No. 3411). The observer, Herr Leo Brenner, saw altogether 126 canals, 31 of which were new, while 13 and 82 were Lowell's and Schiaparelli's respectively. He gives, in a table, the positions of these new canals, remarking that he never saw any of the canals doubled. Five new seas were seen by him at positions B = 162° and +32°, C = 261° and +36°, D = 270° and +48°, E = 201° and +27°, 4 = 215° and +3°. The sea E had been previously seen by Antoniadi, who thought that it represented a doubling of Trivium. Propontis was seen doubled, the old one lying to the westward. On September 8 the last was seen of the south polar snow, and on the same date the north pole was distinctly observed. Nilosyrtis was bridged over as shown in Schiaparelli's map of the year 1882, but further to the south than is shown there. Several other points of interest were noted. A full account of these will be published in the *Kais. Akademie der Wissenschaft.*

In the same number of the *Astr. Nachr.*, mentioned above, M. V. Cerulli gives a brief account of his observations on Mars, made between October 1896 and January of this year.

DOUBLE-STAR MEASURES.—The *Astronomical Journal* (No. 397) gives the measures of several observers of double-stars. Prof. W. J. Hussey contributes measures of eighty different doubles made with the 12-inch and 36-inch of the Lick Observatory. The Morrison Observatory adds several more, measured by Mr. Henry S. Pritchett with the 12½-inch of that observatory. Mr. W. S. Eichelberger, of the Wesleyan University Observatory, Middletown, also publishes a few measures, but does not state the size of the instrument employed. Several bright objects among the southern stars, which have hitherto been supposed to be single, have now been proved to be double, according to Prof. T. J. J. See (*Astr. Nach.*, No. 3312). Further, several wide pairs have been resolved into triple systems of high interest. Three special cases of the former are mentioned, and as they seem likely to be of interest to other observers, we give the following data:—

ψ *Velorum*, discovered 1897 January 31.
α = 9h. 26m. 46·6s. δ = − 40° 1′ 50″·5 (1900·0
1897·084. Pos. angle 258°·8. Dist. 0″·54.
Mag. 5 and 5·1. Both yellow.

p Velorum, discovered 1897 January 10.
α = 10h. 33m. 6·5s. δ = − 47° 42′ 3″·9.
1897·065. Pos. angle 268°·9. Dist. 0″·47.
Mag. 4·6 and 5·2. Both yellow.

λ *Lupi*, discovered 1897 February 1.
α = 15h. 2m. 7·2s. δ = − 44° 53′ 31″·5.
1897·085. Pos. angle 178°·6. Dist. 0″·30.
Mag. 4·9 and 5·2. Both yellow.

BELGIUM OBSERVATORY ANNUAL.—The director of the Royal Belgium Observatory brings together in the annual for this year (the sixty-fourth year) a mass of useful information which will be serviceable to meteorologists as well as astronomers. In addition to the usual solar and planetary ephemerides, occultations, &c., Prof. F. Folie has written some short chapters on the following points:—A reaction in astronomy, accurate history of the discovery of diurnal nutation, explanations of the systematic differences between the Greenwich,

Melbourne, and Cape catalogues by the diurnal nutation and the annual displacement of the pole of inertia, the probability of the existence of diurnal nutation from observations, Chandler's formulæ for computing the variations of latitude, planetary aberration, and the new method of reckoning time (one to twenty-four hours) on the railways. All that one can desire to know about the weather in Belgium during the past year will be found in the excellent summary given by the meteorological director of the observatory, M. A. Lancaster. Several interesting plates are given in his summary. Towards the end of the book various miscellaneous tables and yearly summaries will be found of general interest.

THE JAMES FORREST LECTURE—BACTERIOLOGY.

DR. G. SIMS WOODHEAD, Director of the Laboratories of the Conjoint Board of the Royal Colleges of Physicians and Surgeons, delivered the James Forrest Lecture before the Institution of Civil Engineers on March 18.

After a short introduction, the lecturer sketched briefly the history of bacteriology, and gave an account of Leeuwenhoek's observations, some of which were either directly or through his friends communicated to the Royal Society of London. The organisms described by Leeuwenhoek, in 1683, "were so small that they did not appear larger than represented at E (giving a copy of the figure). The motion of these little creatures, one among another, may be imagined like that of a great number of gnats or flies sporting in the air. From the appearance of these, to me, I judged that I saw some thousands of them in a portion of liquid no larger than a grain of sand, and this liquid consisted of eight parts water, and one part only of the before-mentioned substance taken from the teeth." Leeuwenhoek's microscopes magnified from 40 to 160 times. At that time he had not made up his mind as to the exact nature of these organisms; he spoke of them as living animalculæ, but in some of them he was unable to detect the slightest movement or any sign of life, nor did he theorise as to the meaning of the presence of these organisms in the situation in which he found them, though later, in 1713, he appeared to be under the impression that the organisms seen in the teeth were conveyed into the mouth by drinking-water that had been stored in barrels.

The various forms of bacteria were then briefly described, their size, structure, and mode of growth. Alterations in form were noted, and the marked differences, not only in minute structure, but in mode of growth, and in the nature of their products were indicated. The modifications in the sheath or covering of these organisms were demonstrated, and the frog, spawn, or living glue masses were explained. Fine flagella were shown in organisms that differed very widely as to their nature and functions, and it was pointed out that, from what we know, however, of other flagella and cilia, and from recent observations on the arrangement of the pores in the membrane, and the relation of the flagella to these pores, it is to be anticipated that they are usually, at any rate, processes directly continuous with the central protoplasm of the organism. At one time it was supposed that these flagella were formed only in organisms that have a special affinity for oxygen; but within the last couple of years it has been pointed out that the tetanus bacillus, the organism which grows best where free oxygen is excluded, often presents beautiful flagellated forms, although—and this is an important fact—the organism, as pointed out by Kanthack, remains non-motile when examined under the microscope in the presence of oxygen. How it behaves when oxygen is excluded, has not yet been determined. Even those which have an affinity for oxygen appear to lose their flagella as soon as they leave the surface, and no longer require to move about in order to obtain this substance.

Spore formation was fully described, and the great resistance that these "seed" spores present to heat and chemicals was noted. As an example of the importance of this spore formation, what takes place in the case of the splenic fever bacillus that is found in cattle was mentioned. When an ox dies of anthrax there are found in its blood an enormous number of short thick rods, the anthrax bacilli. If a drop of the blood be taken from a blood-vessel immediately after the death of the animal, the rods will be found, on microscopic examination, to contain no spores—that is, there are no bright points in the substance of the rod, and the animal, if buried at once before any blood or discharges from the body can get on to the land where the animal has died, will not be a source of infection; the putrefactive organisms that develop being sufficient to kill off the anthrax bacilli that are in the blood. If, however, the animal be cut into, and blood be allowed to escape so that the organisms come into contact with the air, and the condition of the blood is altered in such a way that the nutritive supply of these organisms is gradually cut off, spores immediately begin to develop in the bacilli, and, as soon as this takes place, it is an exceedingly difficult matter to get rid of the disease; mere burial is certainly not sufficient, as the spores are not affected by the putrefactive organisms and products—they retain their vitality, and only wait for more favourable conditions under which to become again developed into the active and virulent anthrax organism. The knowledge of this fact, of course, has a most important bearing on the treatment of carcases of animals that have succumbed to anthrax. Other forms of spores of a less resistent character have been described; but it is scarcely necessary to do more than mention them, as they are not yet accurately understood.

As to the effects of temperature upon micro-organisms, it has been found that most of the saprophytes (those that grow upon dead matter) flourish most luxuriantly at the ordinary temperature of water, whilst the parasite or disease-producing bacteria grow and multiply most rapidly at the temperature of their animal or plant hosts. Most of these are killed at a temperature of 60° C. (140° F.). Certain bacteria, however, especially those found in soil and river mud, develop readily at 60° or 70° C., and flourish most luxuriantly at 50° C. C. Globig, and also, quite recently, A. Macfadyen, have shown that there are numerous organisms which can exist at temperatures even higher than this, in spite of the fact that they contain no spores. Of the spore-bearing organisms Dr. Woodhead showed the tetanus and anthrax bacilli, both of which are pathogenic or disease-producing, and the bacillus subtilis or hay bacillus, which is found especially in hay infusions, and appears to be associated with the reduction of organic matter in the process of putrefaction.

The production of enzymes, of acids, and of gases was described to indicate what different functions these organisms may have; and the different ways in which the aerobes and anaerobes are able to take the elements they require for their nutrition, and for the carrying on of their special functions, were explained, and the importance of these processes in the transformation and breaking down of dead organic matter insisted upon. In nature the process of disintegration of such matter is divided essentially into three parts. It is necessary (1) to get all solid matter into solution; (2) to supply as large a quantity of oxygen in as short a time as possible to this organic matter; (3) to attack the organic matter in solution by means of micro-organisms, and to so break it up that the various elements of which this complex material is composed may be thrown into an unstable or nascent condition so that the oxygen present may have an opportunity of entering into combination, and of forming what are called oxidised substances. It is evident from what we know of putrefactive processes that these changes may take place in two perfectly different ways. In the one case we have the oxidation taking place directly, all the nascent substances being satisfied by the oxygen of the air, and the splitting up of the organic matter being carried on by aerobic organisms. In such a process of oxidation which takes place in porous soil well supplied with air and moisture, and also in water which is from time to time well saturated with oxygen, it will be found that little or no putrefactive odour is developed. The marsh gas, the sulphuretted hydrogen, and other similar substances as they are set free, rapidly combine with oxygen to form sulphuric acid, carbonic acid and water; the nitrogenous substances in a similar fashion combining to form nitrous and nitric acids. In the soil these acids combine with the various basic substances, lime, magnesia and the like, so that they are rapidly removed and the way is left clear for the formation of fresh batches of the same substances. In anaerobic putrefaction, on the other hand, the process does not go on in this unobtrusive fashion, the anaerobic organisms having, as it were, to wrest their oxygen from the organic molecules because there is no free oxygen present, set up a much greater disturbance, and the products of the decomposition, such as sulphuretted hydrogen, marsh gas and ammonia, are thrown off in an unoxidised condition, and in the free form (*i.e.* no longer in a nascent condition), they remain comparatively stable, and give rise to the odours so characteristic of rapid anaerobic putrefaction.

The action of light and air was discussed and illustrated, and the relation of nitrifying organisms to the enriching of the soil; the effect of certain organisms which have the power of taking nitrogen from the atmosphere, and of conveying it to plants, was also illustrated. The history of Spontaneous Generation was touched upon, especially in so far as the study of this will-o'-the-wisp had led to the advances in our knowledge of bacteriology.

In relation to disease, the part that bacteria play as ultimate causal factors was described as one of prime importance. If bacteriology had done nothing more for us than draw our attention to the concrete specific bacillus as a cause of cholera, or example, so as to allow us to concentrate our attention on special preventive measures, instead of leaving us to wander in the wilderness of "conditions of soil," of "atmospheric influences," of "epidemic waves," and the like, its value would have been amply demonstrated. Without undervaluing in the slightest degree the careful observations that have been made by eminent epidemiologists, whose work has a value which can only be enhanced by what can be added to it by the bacteriologist, it was pointed out that since Koch's investigations have been accepted as trustworthy, and as the basis on which preventive measures may be founded, we in this country, at any rate, through our admirably constituted Local Government Board, with its organised staff of medical officers and inspectors, have been able, without resorting to strict quarantine, to deal with the specific cases of cholera that have been brought to, or have appeared on, our shores in a fashion that even a few years ago could never have been anticipated. It was further insisted that whatever great predisposing causes may be at work, whatever subsoil, atmospheric, or other conditions may be necessary for the production of an epidemic disease in our midst, we have ample evidence that without the introduction of a special and specific causal agent from outside, we have never had an outbreak of this specific infective disease. Of course, in every outbreak there were men who came forward to show, on the one hand, that only Koch has right on his side, and, on the other, that all wisdom lies in Pettenkoffer's theory. But few seem to act as if, whatever they may believe, the observations of both should receive serious consideration. Seasonal variations, temperature, drainage, rise and fall of ground water, all play an important part in determining the conditions of growth of bacteria; whilst, on the other hand, bad ventilation and filth, famine and illness, all predispose patients to attack. But without the specific organisms that actually set up infective diseases, no infective diseases will occur. Celsus, the great physician, taught that predisposing causes alone were insufficient to set up disease; whilst, on the other hand, exciting causes by themselves were powerless to act. But when they came to act in combination, he maintained that they were both sure and far-reaching in the production of disease. The same applies to-day, whether we have to deal with diphtheria, typhoid, cholera, or tuberculosis. Pettenkoffer deals with predisposing causes and conditions, Koch with exciting factors—bacteria. When disease has not yet come amongst us, let us follow Pettenkoffer; but when it is in our midst, or in our immediate vicinity, Pasteur, Koch and Lister are immediately advanced to the position of more trustworthy guides and leaders.

Sixty years ago, the year of the accession of the Queen to the throne, the proof that the yeast plant was a living organism and the cause of the process of fermentation, was almost complete, whilst only a year later the germs of the silkworm disease were observed; but it was not until more than twenty years after that, that Pasteur was able to point out the full import of these discoveries. Pasteur's work on fermentation and on disease, his experiments on attenuation of organisms, on protective inoculation and on curative injection for hydrophobia, have already been referred to, and are so well known that it is unnecessary to do more than mention them. Koch was able, by his new methods of separating organisms and solid media, to go beyond Pasteur in isolating the anthrax bacillus, and in proving to absolute demonstration the relation of the anthrax bacillus to splenic fever. His ingenious methods of cultivating organisms, of staining them in tissues, and of separating the different species, created a new era in bacteriology.

In our own country we owe to Lord Lister the great advances that have been made in the treatment of wounds, by which thousands of lives are yearly preserved, advances which date entirely from his study of bacteria and bacteriology. Antiseptic surgery, like the antitoxic treatment of diphtheria, is based entirely upon the early researches on bacteriology, and its development has followed most closely the advances made in that subject. "As yet no one can say that we have reached even a resting-stage, and it behoves all those who desire to see advances made in the treatment and prevention of disease, whether in the department of protection and cure, with which medicine is specially concerned, or in the preventive department, with which you gentlemen as Civil Engineers have to deal, to continue to follow closely every new fact and every fresh theory arising out of new observations, in order that bacteria and the forces with which they are endowed may be made our well-disciplined servants, instead of being allowed to waste their energies as uncontrolled and uncontrollable masters."

THE PASTEUR MEMORIAL LECTURE OF THE CHEMICAL SOCIETY.

A SPECIAL meeting of the Chemical Society was held on Thursday evening, March 25, when Prof. Percy Frankland, F.R.S., delivered the Pasteur Memorial Lecture. Prof. Frankland commenced his discourse by pointing out that the consideration of Pasteur's work was a subject specially befitting the Chemical Society, inasmuch as he owed the training which enabled him-to master so many and such various problems to that rigorous discipline to which in early years he was subjected in the pursuit of chemistry. Pasteur's interest in this science was exhibited at a very early age, and even when he was a lad at the provincial college of Arbois, his master cherished the ambition that he would one day occupy a chair at the famous École normale in Paris. This hope was well justified, for it was there that Pasteur, as assistant to M. Balard, commenced those epoch-making discoveries which have stimulated researches in, and practically founded, that fascinating and important branch of chemical science known as stereo-chemistry. Perhaps the most conclusive and eloquent testimony which we can have to the profound importance of Pasteur's researches in this direction is the tribute paid to them by one of his greatest followers, Emil Fischer, who acknowledged but a short time since that, despite the immense amount of work which has been subsequently carried out in this field, "there is hardly a new fact of fundamental importance which has been added to his discoveries."

It was at the École normale also that Pasteur, many years later, carried out his brilliant researches on the etiology of diseases. Pasteur was led to turn his attention to the study of fermentation phenomena by his removal to Lille, one of the leading industries of the district being the manufacture of alcohol from beetroot and grain; and in his desire to bring the work of his department into touch with local interests, he commenced that classical series of researches which he continued over a period of twenty years. In this field of inquiry he had his first passage of arms with the great Liebig; it is needless to say how Pasteur emerged victoriously from this contest, and succeeded in demolishing the chemical theory of fermentation processes which had been advanced and supported so eloquently by Liebig and other leading men of science of the day, and building up in its place that theory which the so-called "vitalists" had so long laboured ineffectually to establish. Pasteur's researches on fermentation also proved of enormous commercial benefit to France and the whole world, by indicating improved methods for the manufacture of vinegar, wine, and beer. Moreover, it was in the course of these inquiries that he established that process of preserving liquids by means of heat, now widely known as Pasteurisation. The story of the famous spontaneous generation controversy was told, and Prof. Frankland pointed out how, in pursuing the laborious investigations involved by his entering into this discussion, Pasteur was unconsciously preparing himself for the great work with which his name will always be associated—the inauguration of the modern system of preventive medicine. Already in his researches on diseases in silkworms, undertaken at the pressing request of his friend and former teacher Dumas, Pasteur was specially attracted by the question of contagion; and the valuable experience he gained in this work may be gathered from the fact that in later years, when any one presented himself and begged the privilege of being allowed to work in his laboratory, he used invariably to ask them if they had read his volume on silkworm diseases, and tell them that that was the best preparation they could have for working with him.

The five years which Pasteur spent upon this successful, though harassing, inquiry told terribly upon his health, and he was struck down by a paralytic seizure, from the physical effects of which he never absolutely recovered, though the clearness of his intellect was never for a moment impaired. His researches on silkworm diseases, and his long and intimate contact with fermentation phenomena, gradually paved the way for the momentous step which led him, at the already ripe age of fifty-five, to enter upon the study of diseases in the pursuit of which he was to win his most glorious laurels. Prof. Frankland described how Pasteur, after much hesitation, was led himself to embark upon this quest in consequence of his anxiety lest through exaggerated statements and undue haste in drawing conclusions—a tendency exhibited by many who at this time took up the bacteriological study of diseases—a reaction should be provoked, and the new ideas consequently fall into disfavour. Pasteur commenced his campaign by investigating the disease known as anthrax; but even while carrying on the most elaborate researches on this subject, he was turning in all directions for material to extend his studies on pathological phenomena. He walks the hospitals, armed with sterile vessels, to collect morbid products; he isolates the staphylococcus pyogenes; he visits the Maternity Hospital, and discovers the streptococcus pyogenes, asserting it to be the cause of puerperal fever. But the occupation of discovering pathogenic bacteria, fascinating as it was, could not permanently engross Pasteur's attention, and his ambition, stimulated by the contemplation of Jenner's great discovery, led him to seek a means of securing immunity from those diseases of which the specific viruses had been discovered, similar to that which his great predecessor had secured in the case of small-pox. Pasteur's discovery of a vaccine for fowl cholera was soon followed by vaccines for *Rouget de porc* or swine measles, and for anthrax, the saving to his country by the use of the anthrax vaccine alone having amounted to no less than 280,000*l.* in the course of the ten years from 1884 to 1894. The magnificent triumph which followed the discovery of these vaccines was, however, if possible, eclipsed by the elaboration of a cure for rabies; nearly 20,000 persons have undergone Pasteur's anti-rabic treatment, and the mortality amongst these treated persons has been less than 5 per 1000. The public expression of gratitude for this great discovery, concluded the lecturer, took the form of a general subscription, which rendered possible the foundation of the Institut Pasteur, which its great namesake had long cherished as a dream, and the realisation of which was the delight of his few remaining years; and here, under the auspices of Duclaux, Roux, Chamberland, and Metschnikoff, the sacred fire kindled by *le grand Maître* is still burning. Long may this flame be fed within the temple where now rests in eternal sleep that hero of science, whose greatest ambition was to be able, in his last hour, to pronounce the words, so simple in their form, so boundless in their aspiration, *j'ai fait ce que j'ai pu*.

THE DIAMOND MINES OF KIMBERLEY.[1]

IT is a standing surprise to the watchful outsider how little attention is bestowed on some of our colonies. For instance, to the Cape Colony, comprising vast, varied, and productive regions, we have till recently manifested profound ignorance and consequent indifference. When the Cape Colony was first incorporated with the Empire, it was pronounced "a bauble, unworthy of thanks." Yet before the Suez Canal and the Waghorn overland route to India, the Cape, as commanding our road to India, Australia, and China, had a special importance. Even now it presents an alternative route which under conceivable circumstances may be of capital moment.

The high grounds above Cape Town are rich in medicinal health-giving waters. The districts where these springs occur are high-lying, free from malaria, and admirably adapted for the restoration of invalids. It needs only some distinguished power to set the fashion, some emperor, prince, or reigning beauty to take the baths and drink the waters, and the tide of tourists would carry prosperity to Aliwal North, Fraserburg, Craddock, and Fort Beaufort.

From London to Kimberley by the Cape route is about 6700 miles, and is compassed in three weeks, although I would warmly recommend any one on pleasure bent to do as my wife and I did—spend a few days at Cape Town—before commencing the tedious railway journey to Kimberley.

The famous diamond mines in the neighbourhood are Kimberley, De Beers, Dutoitspan, Bulfontein, and Wesselton. They are situated in latitude 28° 43′ South, and longitude 24° 46′ East. The town itself is 4042 feet above sea-level. Other mines in the neighbourhood are worked for diamonds, but as yet they are unimportant. Kimberley is practically in the centre of the present diamond-producing area. Besides these mines, two others of some importance in the Orange Free State are known as Jagersfontein and Coffeefontein, about sixty miles from the Kimberley diamond region.

Kimberley.

The surface of the country round Kimberley is covered with a ferruginous red, adhesive, sandy soil, which makes horse traffic very heavy. Below the red soil is a basalt, much decomposed and highly ferruginous, from 20 to 90 feet thick, and lower still from 200 to 250 feet of black slaty shale containing carbon and iron pyrites. These are known as the Kimberley shales; they are very combustible, and in a part of the De Beers mine where they were accidentally fired, they smouldered for over eighteen months. Then follows a bed of conglomerate about 10 feet thick, and below the conglomerate about 400 feet of a hard compact rock of an olive colour, called "melaphyre" or olivine diabase. Below the melaphyre is a hard quartzite about 400 feet thick. The strata are almost horizontal, dipping slightly to the north: in places they are distorted and broken through by protruding dykes of trap. There is no water nearer than the Vaal river, about fourteen miles away, and formerly the miners were dependent on rain-water and a few springs and pools. Now, however, a constant and abundant supply of excellent water is served to the town, whilst good brick houses, with gardens and orchards, spring up on all sides. To mark the dizzy rate of progress, Kimberley has an excellent club and one of the best public libraries in South Africa. Parts of the town, affectionately called "the camp" by the older inhabitants, are not beyond the galvanised iron stage, and the general appearance is unlovely and depressing. Reunart reckons that over a million trees have been cut down to supply timber for the mines, and the whole country within a radius of 100 miles has been denuded of wood with the most injurious effects on the climate. The extreme dryness of the air, and the absence of trees to break the force of the wind and temper the heat of the sun, probably account for the dust storms so frequent in summer. The temperature in the day frequently rises to 100° in the shade, but in so dry a climate this is not unpleasant, and I felt less oppressed by this heat than I did in London the previous September. Moreover, in Kimberley, owing to the high altitude, the nights are always cool.

The approach to Kimberley is deadly dull. The country is almost treeless, and the bare veldt stretches its level length, relieved only by distant hills on the horizon.

The Pipes.

The five diamond mines are all contained in a circle 3½ miles in diameter. They are irregularly shaped round or oval pipes, extending vertically downwards to an unknown depth, retaining about the same diameter throughout. They are said to be volcanic necks, filled from below with a heterogeneous mixture of fragments of the surrounding rocks, and of older rocks, such as granite, mingled and cemented with a bluish coloured hard clayey mass, in which famous blue clay the imbedded diamonds are hidden.

The breccia filling the mines, usually called "blue ground," is a collection of fragments of shale, various eruptive rocks, boulders, and crystals of many kinds of minerals. Indeed, a more heterogeneous mixture can hardly be found anywhere else on this globe. The ground mass is of a bluish-green, soapy to the touch, and friable, especially after exposure to the weather. Prof. Maskelyne considers it to be a hydrated bronzite with a little serpentine. Besides diamonds, Moissan has detected more than eighty species of minerals in the blue ground, the more common being:—Magnetite, ilmenite, garnet, bright green ferriferous enstatite (bronzite), a hornblendic mineral closely resembling smaragdite, calc-spar, vermiculite, diallage, jeffreysite, mica, kyanite, augite, peridot, iron pyrites, wollastonite, vaalite, zircon, chrome iron, rutile, corundum, apatite, olivine, sahlite, chromite, pseudobrookite, perofskite, biotite, and quartz. The

[1] Two lectures delivered at the Imperial Institute, on November 16 and December 7, 1896, by Dr. William Crookes, F.R.S.

blue ground does not show any signs of passing through great heat, as the fragments in the breccia are not fused at the edges. The eruptive force was probably steam or water-gas, acting under great pressure, but at no high temperature. According to Mr. Dunn, in the Kimberley mine, at a depth of 120 feet, several small fresh-water shells were discovered in what appeared to be undisturbed material.

The rock outside the pipes and encasing them is called "reef." Inside some of the mines occur large masses of "floating reef," covering an area of several thousand square feet. In the De Beers mine is what is called "the snake," a dyke of igneous rock taking a serpentine course across the mine, and standing like a vein nearly vertical, varying in thickness from 2 to 7 feet.

The areas of the mines are :—

Kimberley	33 acres
De Beers	22 ,,
Dutoitspan	45 ,,
Bulfontein	36 ,,

Before the discovery of the mines there was nothing in the superficial appearance of the ground to indicate the treasures below. Since the volcanic ducts were filled with the diamantiferous ground, denudation has planed the surface and the upper parts of the craters, and other ordinary signs of volcanic activity being smoothed away, the superficial and ubiquitous red sand covered the whole surface. The Kimberley mine seems to have presented a slight elevation above the surrounding flat country, while the sites of other mines were level or even slightly depressed. The Wesselton mine, within a mile of Dutoitspan, has only been discovered a few years. It showed a slight depression on the surface, which had been used as a shoot for dry rubbish. There are other diamantiferous pipes in the neighbourhood, but they are small, and do not contain stones in payable quantities. More recently another diamantiferous pipe has been discovered about forty miles off, near Klipdam, and is now worked as the Leicester mine. Other hoards of diamonds may also be near ; where there are no surface signs, and the pipe itself is hidden under 10 or 20 feet of recent deposits, it is impossible to prospect the entire country. Accident has hitherto been the chief factor in the discovery of diamond mines.

How the great pipes were originally formed is hard to say. They were certainly not burst through in the ordinary manner of volcanic eruption, since the surrounding and enclosing walls show no signs of igneous action, and are not shattered or broken up even when touching the "blue ground." It is pretty certain these pipes were filled from below after they were pierced, and the diamonds were formed at some previous time and mixed with a mud volcano, together with all kinds of débris eroded from the rocks through which it erupted. The direction of flow is seen in the upturned edges of some of the strata of shale in the walls, although I was unable to see any upturning in most parts of the walls of the De Beers mine at great depths.

The Kimberley mine is filled for the first 70 or 80 feet with what is called "yellow ground," and below that with "blue ground." This superposed yellow on blue is common to all the mines. The blue is the unaltered ground, and owes its colour chiefly to the presence of lower oxides of iron. When atmospheric influences have access to the iron it is peroxidised, and the ground assumes a yellow colour. The thickness of yellow earth in the mines is therefore a measure of the depth of penetration of air and moisture. The colour does not affect the yield of diamonds.

The contents of the several pipes are not absolutely identical. The diamonds from each pipe differ in character, showing that the upflow was not simultaneous from one large reservoir below, but the result of several independent eruptions. Even in the same mine there are visible traces of more than one eruption.

The blue ground varies in its yield of diamonds in different mines, but it is pretty constant in the same mine. In 1890, the yield per load of blue ground was—

From the Kimberley mine	from 1·25	to 1·5	carats.
,, De Beers mine	,, 1·20	,, 1·33	,,
,, Dutoitspan mine	,, 0·17	,, 0·5	carat.
,, Bulfontein mine	,, 0·5	,, 0·33	"

Both in Kimberley and De Beers the blue ground on the west side is poorer in diamonds than the blue ground in other parts of the mines. The diamonds from the west side also differ somewhat from those in other parts of the same mine. The diamonds from each mine have a distinctive character ; so uniform are the characteristics that an experienced buyer can tell at once the locality of any particular parcel of stones. De Beers and Kimberley mines are distinguished by the yield of large yellowish crystals. Dutoitspan yields mainly coloured stones, while Bulfontein—half a mile off—produces small white stones, occasionally speckled and flawed, but rarely coloured. The diamonds from the Wesselton mine are nearly all irregular in shape ; a perfect crystal is rare, and most of the stones are white, few yellow. The diamonds from the Leicester mine have a frosted, etched appearance ; they are white, the crystallisation irregular ("cross-grained"), and they are very hard. Stones from Jagersfontein, in the Orange Free State, display great purity of colour and brilliancy ; they have that so-called "steely" lustre characteristic of old Indian gems. Stones from this mine are worth nearly double those from Kimberley and De Beers.

In the first days of diamond mining there was no idea that diamantiferous earth extended to any particular depth, and miners were allowed to dig holes at haphazard, and prospect where they liked. When the Kimberley mine was discovered, a new arrangement was made, and in July 1871 it was cut up into about 500 claims, each 31 feet square, with spaces reserved for about fifteen roadways across the mine. No person at first could hold more than two claims—a rule afterwards modified.

It may help to realise the enormous value of the Kimberley mine if I tell you that two claims, measuring together 62 by 31 feet, and worked to a depth of 150 feet, yielded 28,000 carats of diamonds.

The roadways across the mine soon, however, became unsafe. Claims were sunk 100 or 200 feet each side of a roadway, and the temptation to undermine roadways was not always resisted. Falls of road frequently took place, followed by complete collapse, burying mine and claims in ruin. At that time there were probably 12,000 or 15,000 men at work in the mine, and then came the difficulty how to continue working the host of separate claims without interference with each other.

The mine was now threatened in two other quarters. The removal of the blue ground took away the support from the walls of the pipe, and frequent falls of reef occurred, not only covering up valuable claims with rubbish, but endangering the lives of workers below. Moreover, as the workings deepened, water made its appearance, necessitating pumping. In 1878 one quarter of the claims were covered by reef, and in 1879 over 300,000*l.* were spent on removing reef and water. In 1881 over 200,000*l.* were thus spent, and in 1882 more than half a million sterling was needed to defray the cost of reef removal. So matters went on until four million cubic yards of reef had been removed, at a cost of two millions sterling, and still little good was done, for out of 400 claims in the mine, only about 50 could be regularly worked. Ultimately, in November 1883, the biggest fall of reef on record took place, estimated at 250,000 cubic yards, surging half across the mine, where the bulk of it lies to this day. It became evident that open workings could not be carried on at such depths, and after many experiments the present system of underground working was devised.

During this time of perplexity, individual miners who could easily have worked one or two claims near the surface could not continue work in the face of harassing difficulties and heavy expenses. Thus the claims gradually changed hands, until the mine became the property first of a comparatively small number of capitalists, then of a smaller number of limited liability companies, until finally the whole of the mines have practically become the property of the "De Beers Consolidated Mines, Limited."

Underground Workings.

The system of underground working in use at the time of my visit is as follows :—Shafts are sunk in the solid rock at a sufficient distance from the pipe to be quite safe against reef movements in the open mine. The main shaft at De Beers starts about 540 feet from the north side of the mine, and is now over 1500 feet deep. Tunnels are driven from this shaft at different levels to cross the mine from west to east, about 120 feet apart. These tunnels are connected with each other by two tunnels running north and south, one near the west side of the mine and one midway between it and the east margin.

of the mine. From the east and west tunnels offsets are driven to the surrounding rock. When near the rock, they are widened into galleries, these in turn being stoped on the sides until they meet, and upwards until they break through the blue ground. The fallen reef with which the upper part of the mine is filled, sinks and partially fills the open space. The workmen then stand on the fallen reef, and drill the blue ground overhead; as the roof is blasted back the débris follows. When stoping between two tunnels, the blue is stoped up to the débris about midway between the two tunnels. The upper levels are worked back in advance of the lower levels, and the works assume the shape of irregular terraces. The main levels are from 90 to 120 feet apart, with intermediate levels every 30 feet. Hoisting is done from only one level at a time through the same shaft. By this ingenious method of mining, every portion of blue ground is excavated and raised to the surface, the rubbish on the top gradually sinking down and taking its place.

The scene below ground in the labyrinth of galleries is bewildering in its complexity, and is about as little like one's idea of a diamond mine as can well be conceived. Electric light is universal in the workings. One set of workers attends to the rock-drilling machines for blasting the blue ground; in other parts the blue is shovelled into wagons, which, when filled, are carried along rails by moving ropes till they get to the gallery, where the contents are sent to the surface.

At the bottom of the main shaft, at the 1300-foot level, the galleries converge to a large open space where the tram lines carrying the trucks meet. In front is a shoot to which the trucks full of blue ground are rapidly wheeled, tipped over, their contents discharged, when they are shunted to make way for other trucks. At the foot of the shoot is a skip holding 64 cubic feet, or four truck-loads. As soon as a skip has received its allotted four loads an electric bell sounds at the engine house, when the skip is hoisted to the surface and another takes its place. So the work proceeds, and on busy days ground has been hoisted at the rate of 20 loads every three minutes, equal to 400 loads an hour. In 1894 the record hoisting of blue ground at the Kimberley mine was 470 loads an hour; in one shift of eight hours 3312 loads; and in a day of three shifts, 7415 loads.

All below ground is dirty, muddy, grimy; half-naked men, black as ebony, muscular as athletes, with perspiration oozing from every pore, are seen in every direction, hammering, picking, shovelling, wheeling the trucks to and fro, keeping up a weird chant, which rises in force and melody when a titanic task requires excessive muscular strain. The whole scene is far more suggestive of a coal mine than a diamond mine, and all this mighty organisation, this strenuous expenditure of energy, this clever, costly machinery, this ceaseless toil of skilled and black labour, going on day and night, is just to win a few stones wherewith to deck my lady's finger!

At the four mines about 8000 persons are daily employed, namely, 1500 whites and 6500 blacks. The wages are—whites, 5*l.* or 6*l.* a week; blacks, underground, 4*s.* to 5*s.* a day, and above ground 21*s.* a week.

With gems like diamonds, where so large an intrinsic value is concentrated into so small a bulk, it is not surprising that robbery has to be guarded against in the most elaborate manner. The Illicit Diamond Buying (I.D.B.) laws are very stringent, and the searching, rendered easy by the "compounding" of the natives—which I shall describe presently—is of the most drastic character. It is, in fact, very difficult for a native employé to steal diamonds; even were he to succeed, it would be almost impossible to dispose of them, as a potential buyer would prefer to secure the safe reward for detecting a theft rather than run the serious risk of doing convict work on the Cape Town Breakwater for a couple of years.

The Depositing Floors.

Owing to the refractory character of blue ground fresh from the mines, it has to be exposed to atmospheric influences before it will pulverise under the action of water and mechanical treatment.

From the surface-boxes, into which the blue ground is tipped when it reaches the top of the main shaft, it is transferred to side-tipping trucks, and sent to the depositing floors by means of endless wire-rope haulage.

The depositing floors are prepared by removing the bush and grass from a fairly level piece of ground; this ground is then rolled smooth and hard. The floors extend over many square miles of country, and are surrounded by 7-foot barbed wire fences, vigilantly guarded day and night. The De Beers floors, on Kenilworth, are laid off in rectangular sections 600 yards long and 200 yards wide, each section holding about 50,000 loads. The ground from the Kimberley mine is the softest, and only needs a few months' exposure on the floors; the ground from De Beers is much harder, and requires at least six months' exposure; while some ground is so hard that it will not disintegrate by exposure to the weather under one or two years. The De Beers mine contains a much larger quantity of this hard blue ground than the other mines, and, in order to save the loss of time consequent on keeping an enormous stock of blue constantly on the floors, it has recently been decided to pass the harder and more refractory stuff direct from the mine through crushing mills.

For a time the blue ground remains on the floors without undergoing much alteration. But soon the heat of the sun and moisture produce a wonderful effect. Large pieces, hard as ordinary sandstone when taken from the mine, commence to crumble. At this stage the winning of the diamonds assumes more the nature of farming than mining. The ground is frequently harrowed and occasionally watered, to assist pulverisation by exposing the larger pieces to atmospheric influences. The length of time necessary for the ground to weather before it becomes sufficiently pulverised for washing depends on the season of the year and the amount of rain. The longer the ground remains exposed the better it is for washing.

In June 1895, the quantity of blue ground on the floors was 3,360,256 loads, representing diamonds to the value of nearly one million sterling. The risk of robbery at this stage of the operations is somewhat serious, and precautions are correspondingly elaborate. A native working on the floors may come across a large stone and secrete it about his person. Careful search soon reveals this crude form of robbery. Or he may hide it, note its position in the field, and after working hours creep back and furtively secure the prize. As a safeguard five powerful search-lights, each of 25,000 candle-power, sweep across the floors all night, and guards are on the watch to prevent any unauthorised person entering the mining area, and to prevent natives who are working at night from leaving the floors without being seen.

Washing and Concentrating Machinery.

After the blue ground has been weathered for a sufficient time, it is again loaded into trucks and hauled to the washing machinery.

About 14 per cent. of all the ground sent to the depositing floors are too hard to weather, so of late years crushing and concentrating plant has been erected to deal effectually with the hard lumps, thus saving the great lock-up of capital consequent on letting them lie on the floor a year or two.

The hard lumps being hauled to the upper part of the machine, are tipped into bins, whence they pass to crushing rollers which so reduce them that they will pass through a ring two inches in diameter. The coarse powder is screened through revolving cylinders having $\frac{1}{2}$ inch and $1\frac{1}{4}$ inch perforations. The stuff passing through the finer holes goes to the finishing mill, while the coarser stuff goes to smaller crushers. Before the coarse lumps are re-crushed they pass over revolving picking tables, where any specially large diamonds are rescued, thus preventing the risk of breakage. Finally the crushed and graded stuff goes to a series of jigs, and after further concentration the diamantiferous gravel is taken in locked trucks to the pulsators.

The Pulsator.

The pulsator is an ingeniously designed but somewhat complicated machine for dealing with the diamantiferous gravel already reduced one hundred times from the blue ground; the pulsator still further concentrating it till the gravel is rich enough to enable the stones to be picked out by hand. The value of the diamonds in a load of original blue ground being about 30*s.*, the gravel sent to the pulsator from the pans, reduced a hundredfold, is worth 150*l.* a load. Stuff of this value must not be exposed to risk of peculation. The locked trucks are hoisted by a cage to a platform, where they are unlocked, and their contents fed into a shoot leading to a cylinder. This cylinder is covered with iron plates perforated in sections with four sizes of round holes, $\frac{1}{8}$ inch, $\frac{5}{16}$ inch, $\frac{1}{4}$ inch, and $\frac{3}{8}$ inch in diameter. That portion of the deposit too coarse to pass through the $\frac{3}{8}$-inch

holes issues at the end of the cylinder, whence it goes direct to the sorting house. The four sizes which pass through the screens flow to the same number of jigs. The bottoms of the jigs are covered with screens the meshes of which are respectively $\frac{1}{8}$ inch, $\frac{3}{16}$ inch, $\frac{1}{4}$ inch, and $\frac{3}{8}$ inch square, thus corresponding with, but being a little coarser than the holes in the cylinder. Upon each screen is spread a layer of bullets to prevent the rich deposit from passing too rapidly through the screens. The jigs themselves are stationary, but from below an intermittent stream of water passes in rapid pulsations with an up and down movement. This pulsation keeps the diamantiferous gravel constantly moving—"alive" is the expressive word used—and tends to sort out the constituents roughly according to their specific gravity, the heavier particles working to the bottom and the lighter material washing off by the flow of water and passing into trucks, whence it is carried to the tailings heap. The heavier portions by the up and down wash of the water gradually work their way under the bullets and pass through the screens into pointed boxes, whence the contents are drawn off at intervals and taken to the sorting room.

Sorting out.

The sorting room in the pulsator house is long, narrow, and well lighted. Here the rich gravel is brought in wet, a sieve-full at a time, and is dumped in a heap on tables covered with iron plates. The tables at one end take the coarsest lumps, next comes the gravel which passed the $\frac{3}{4}$ inch holes, then the next in order, and so on. The first sorting is done by thoroughly trustworthy white men; for here the danger of robbery is greatest. Sweeping the heap of gravel to the right, the sorter scrapes a little of it to the centre of the table by means of a flat piece of sheet zinc. With this tool he rapidly passes in review the grains, seizes the diamonds and puts them into a little tin box in front of him. The stuff is then swept off to the left, and another lot taken, and so on till the sieve-full of gravel is exhausted, when another is brought in. The stuff the sorter has passed to his left as temporarily inspected is taken next to another part of the room, where it is again scrutinised by native convicts again and again, and whilst diamonds can be found in quantity sufficient to repay the cost of convict labour, it is passed under examination.

The diamond has a peculiar lustre, and on the sorter's table it is impossible to mistake it for any other stone that may be present. It looks somewhat like clear pieces of gum arabic, with a sort of intrinsic lustre which makes a conspicuous shine among the other stones.

Besides diamonds, the following associated minerals reach the sorting tables:—

Pyrope (garnet), sp. gr. 3·7, containing from 1·4 to 3 per cent. of oxide of chromium; zircon, in flesh-coloured grains, but no crystals, sp. gr. 4 to 4·7; kyanite, sp. gr. 3·45 to 3·7, discernible by its blue colour and perfect cleavage; chrome diopside, sp. gr. 3·23 to 3·5, of a bright green colour; bronzite, sp. gr. 3·1 to 3·3; magnetite, sp. gr. 4·9 to 5·2; mixed chrome and titanium iron ore, sp. gr. 4·4 to 4·9, containing from 13 to 61 per cent. of oxide of chromium, and from 3 to 68 per cent. of titanic acid, in changeable quantities; hornblende, sp. gr. 2·9 to 3·4; barytes, sp. gr. 4·3 to 4·7; and mica.

In the pulsator and sorting house most of the native labourers are long sentence convicts, supplied with food, clothing, and medical attendance by the company. These men are necessarily well guarded, and all the white men in the works carry revolvers. I myself saw about 1000 convicts at work. I was told that insubordination is very rare. Apart from the hopelessness of a successful rising, there is little inducement to revolt; the lot of these diamond workers is preferable to life in the Government prisons, and they seem contented.

Sometimes as many as 5000 carats of diamonds come from the pulsator in one day, representing about 10,000*l.* in value.

Prodigious diamonds are not so uncommon as is generally supposed. Diamonds weighing over an ounce (151·5 carats) are not unfrequent at Kimberley, and, were it necessary, there would be no difficulty in getting together a hundred of them. Not long ago, in one parcel of stones at Wernher, Beit, and Co.'s office, I saw eight perfect ounce crystals, and one weighing two ounces. The largest diamond from the Kimberley mines weighed 428½ carats, or nearly 4 ounces troy. It measured 1¾ inch through the longest axis, and was 1½ inch square. After cutting, it weighed 228½ carats, losing 200 carats in the process. The largest known diamond weighs 970 carats—over half a pound. It was found at the Jagersfontein mine. Diamonds smaller than a small fraction of a grain elude the sorters and are lost. A microscopic examination of blue ground from Kimberley, after treatment with appropriate solvents, shows the presence of microscopic diamonds, white, coloured, and black, also of boart and carbonado.

The Diamond Office.

From the pulsator the diamonds are sent to the general office in Kimberley to be cleansed in a boiling mixture of nitric and sulphuric acids. A parcel of diamonds loses about half a part per 1000 by this treatment.

After purification, the diamonds are handed to the valuators, who sort them into classes, according to size, colour, and purity. In the diamond office they are sorted into ten classes. In the year 1895 in 1141·8 carats of stones, the proportions of the different classes were as follows:—

Close goods (best stones)	53·8
Spotted stones	75·8
Fine cleavage	79·1
Flats	39·5
Macles	36·5
Ordinary and rejection cleavage	243·4
Rejection stones	43·2
Light and brown cleavage	56·9
Rubbish	371·8
	1000·0
Fine sand	141·8
	1141·8

From two to three million carats of diamonds are turned out of the De Beers mines in a year, and as five million carats go to the ton, this represents half a ton of diamonds. To the end of 1892, ten tons of diamonds had come from these mines, valued at 60,000,000*l.* sterling. This mass of blazing diamonds could be accommodated in a box five feet square and six feet high.

In the year ending June 1895, there were found 2,435,541½ carats of diamonds, realising 3,105,958*l.* During the same time the total expenditure amounted to 1,704,813*l.*, leaving a profit of 1,401,145*l.*

About half these expenses represent mine wages or other local expenses.

The De Beers Company could raise many more diamonds, but a superfluity would have the effect of lowering the price. The diamond is a luxury, and there is only a limited demand for it throughout the world. From 4 to 4½ millions sterling is as much as is spent annually in diamonds; if the production is not regulated by the demand, there will be over-production, and the trade will suffer. By regulating the output the directors have succeeded in maintaining prices since the consolidation in 1888.

Diamonds to the value of about a million annually are produced by outside companies and individuals.

The Compound System.

One great safeguard against robbery is the "compound" system of looking after the natives. A "compound" is a large square, about 20 acres in extent, surrounded by rows of one-storey buildings of corrugated iron. These are divided into rooms holding each about twenty natives. A high iron fence is erected around the compound, 10 feet from the buildings. Within the enclosure is a store, where the necessaries of life are supplied to the natives at a reduced price, wood and water being provided free of charge. In the middle is a large swimming-bath, with fresh water running through it. The rest of the space is devoted to recreation, games, dances, concerts, and any other amusement the native mind can desire. In case of accident or illness there is a well-appointed hospital, where the sick are tended. Medical supervision, nurses, and food are supplied free by the Company.

In the compound are to be seen nearly all the best types of African tribes. Each tribe keeps to itself, and to go round the buildings skirting the compound is an admirable object-lesson in ethnology. At one part is a group of Zulus; next we come to Fingoes; then Basutos; beyond come Matabele, Bechuanas, Pondos, Shangains, Swazis, and other less-known tribes, each

forming a group by itself, or wandering about making friendly calls.

The clothing in the compound is diverse and original. Some of the men are great dandies; others think that in so hot a climate a bright coloured pocket-handkerchief is as great a compliance with the requirements of civilisation as can be expected.

They get very good wages, varying according to the work. The work is appreciated, and there are always more applicants than can be accepted. On entering, the restrictions to which they must submit are fully explained, and they are required to sign for three months at least, during which time they must not leave the compound or mine. A covered way and tunnel lead the workers underground to the down shaft, while those working on the depositing floors go and come under guard. It is seldom that a man does not return, once he has lived the life in the compound; some come again and again for years, only leaving occasionally to spend accumulated savings. Some of the careful men contrive to save money. They carry it at intervals to Captain Dallas to keep for them. Occasionally they ask to look at their savings, which may amount to 30*l.* or 40*l.*, accumulated by driblets. They are ignorant of savings banks or interest, and are content if they see their own money in the original rags and papers in which it was handed in. Sometimes Captain Dallas will have as much as 1000*l.* of these savings in his care. On leaving, the men generally draw all their savings, and it is not uncommon for a grateful Kaffir to press 2*l.* or 3*l.* on Captain Dallas in recognition of his trouble. They are astonished when their offerings are declined; still more so when it is explained that if they would put their savings in a bank, they would have a few extra pounds given to them for the privilege of taking care of it. Bank accounts are beyond them. The Kaffir, on demand, must behold his coins just as he handed them in, wrappings and all.

So much then for the diamond mining industry of Kimberley as I found it on my visit in the early part of 1896. I trust I have made you realise something of the daily life of the diamond miners, of the skill and ingenuity with which their labours are controlled, and of the vicissitudes through which a diamond must pass before it is fit to blaze in a ring or a tiara.

As for myself, I like to look back on our visit, and I am glad we made the journey. I like to recall the dusky natives at work and at play, with their smiling, good-natured faces. And I am glad to have seen that Arabian Nights vision, the strong room of the De Beers Company, literally heaped with stones won from the blue ground, purified, flashing, and of inestimable price, ready to play their part in the lives of men and women. And above all, I like to recall the friendly welcome, the thousand acts of kindness shown us by our able and enterprising colonial fellow countrymen.

The Diamond.

I will briefly survey the chief chemical and physical characteristics of the diamond. I need scarcely say it is almost pure carbon, and is the hardest substance in nature. When heated in air or oxygen to a temperature varying from 760° to 875° C., according to its hardness, the diamond burns with production of carbonic acid. It leaves an extremely light ash, sometimes retaining the shape of the crystal, consisting of iron, lime, magnesia, silica, and titanium. In boart and carbonado, the amount of ash sometimes rises to 4 per cent., but in clear crystallised diamonds it is seldom higher than 0·05 per cent. By far the largest constituent of the ash is iron.

The specific gravity of the diamond is from 3·514 to 3·518. For comparison, I give in tabular form the specific gravities of the different varieties of carbon:—

Amorphous carbon	1·45 to 1·70
Graphite	2·11 ,, 2·26
Hard gas coke	2·356
Boart	3·47 ,, 3·49
Carbonado	3·50
Diamond	3·514 ,, 3·518

The diamond crystallises in octahedra. It frequently occurs with curved faces and edges. Twin crystals (macles) are not uncommon. The crystals frequently contain microscopic cavities, and Brewster, by means of polarised light, found that the diamond round these cavities showed evidence of strain, as if from the presence of included gas at high pressure.

Some crystals of diamonds have their surfaces beautifully marked with equilateral triangles, interlaced and of varying sizes. Under the microscope these markings appear as shallow depressions sharply cut out of the surrounding surface, and these depressions were supposed by Gustav Rose to indicate the probability that the diamonds had at some previous time been exposed to incipient combustion. Rose pointed out that similar triangular striations appeared on the surfaces of diamonds burnt before the blowpipe. I have satisfied myself that during combustion before the blowpipe, in the field of a microscope, the surface is etched with triangular markings very different in character from those naturally on crystals. The artificial striæ are much smaller and massed closer together, looking as if the diamond during combustion flaked away in triangular chips, while the markings natural to crystals appear as if produced by the crystallising force as they were being built up. Many crystals of chemical compounds, alum, for instance, appear striated from both these causes. Geometrical markings can be produced by eroding the surface of a crystal with water, and they also occur naturally during crystallisation.

Some diamonds have enclosed in their substance black uncrystallised particles of graphite. There also occur what may be considered intermediate forms between the well-crystallised diamond and graphite. These are "boart" and "carbonado." Boart is an imperfectly crystallised form of diamond, having no clear portions, therefore being useless for gems. Boart is frequently found in spherical globules, and may be of all colours. Being very hard it is used in rock-drilling, and, when crushed, for cutting and polishing other stones. Carbonado is the Brazilian term for a still less perfectly crystallised form of carbon. It is equally hard, and occurs in porous masses, and in massive black pebbles, sometimes weighing a couple or more ounces.

Many diamonds after exposure for some time to the sun give out light when viewed in a dark room. Some diamonds are fluorescent, appearing milky in sunlight. In a vacuum, exposed to a high-tension current of electricity, diamonds phosphoresce of different colours. In these circumstances most South African diamonds shine with a bluish light. Diamonds from other localities shine with different colours, such as bright blue, apricot, pale blue, red, yellowish green, orange, and pale green. The most phosphorescent diamonds are those which are fluorescent in the sun. One beautiful green diamond in my collection, when phosphorescing in a good vacuum, gives almost as much light as a candle; the light is pale green—almost white.

During molecular bombardment the diamond becomes discoloured, and in course of time becomes black on the surface. Some diamonds blacken in the course of a few minutes, while others require an hour or more to discolour. This blackening is only superficial, and although no ordinary means of cleaning will remove the discolouration, it goes at once when the stone is polished with diamond powder. Ordinary oxidising reagents have little or no effect in restoring the colour. The black stain on the diamond is not due to a layer of amorphous carbon, but to graphite, which is much more resistent to oxidation. It is not necessary to expose the diamond in a vacuum to electrical excitement in order to produce a change. Some diamonds phosphoresce when exposed to the sun's rays or to an electrical discharge in the air, and many more are phosphorescent when exposed to the Röntgen rays. In the latter case a slight superficial blackening also takes place.

The diamond is remarkable in another respect. It is extremely transparent to the Röntgen rays, whereas highly refracting glass, used in imitation diamonds, is almost perfectly opaque to them. I exposed a flat plate of diamond, 0·0786 inch thick, and in shape a perfect equilateral triangle, side by side with a piece of glass of the same shape and thickness, over a photographic plate to the X-rays for a few seconds. On development the impression was found to be very feeble where the diamond obscured the rays, showing that most passed through, while the glass was seen to have obstructed all of them.

By this means imitation diamonds and some other false gems can readily be identified and distinguished from the true gems.

Diamonds occur in all shades, from deep yellow to pure white and jet black, from deep brown to light cinnamon, also green, blue, pink, yellow, orange, and opaque.

I have shown how interesting is Kimberley with reference to its buried diamond wealth. The enormous find and exportation of diamonds must bring reciprocal benefit; and it would redound to our credit could we honourably do our part towards the pacification and development of the colony.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Prof. W. J. Sollas, F.R.S., Professor of Geology in the University of Dublin, and late Fellow of St. John's College, Cambridge, has been elected to succeed the late Prof. Green as Professor of Geology.

In a Convocation to be held on Tuesday, May 11, the decree will be proposed that the gift of a very large and valuable collection of butterflies, offered by Mr. F. du Cane Godman, F.R.S., and Mr. Osbert Salvin, F.R.S., to the Hope Department, be accepted by the University. Prof. E. B. Poulton, the Hope Professor, states that the specimens in this collection are of especial value because of the excellent geographical data which accompany them. Although specimens from all countries are included, the collection is especially rich in species from Central America, a district of peculiar interest, hitherto but poorly represented in the Hope Collection. Many specimens of historic interest are also present—the captures of Bates in Brazil, of Belt in Nicaragua, and of Wallace in the Malay Archipelago. The majority of the more recently captured specimens were taken by the greatest living collectors, such as G. C. Champion and H. H. Smith (Central America), and C. M. Woodford (Solomon Islands); so that all localities can be entirely depended upon. No conditions are attached to the gift, so that the specimens can be at once incorporated with those of the General Collection, as soon as they have been adequately labelled. The collection also contains a large amount of material which will be available to illustrate the principles of protective mimicry, geographical distribution, isolation, &c.

AN anonymous donor has given 25,000 dols. to the Brooklyn Polytechnic Institute.

DR. WALLIS BUDGE has received the *ad eundum* degree of D.Litt. from the University of Durham.

THE chair of Natural Philosophy in Queen's College, Belfast, vacant by the retirement of Prof. Everett, has been filled by the appointment of Mr. W. B. Morton, of Queen's College, Belfast, and St. John's College, Cambridge.

THE Congrès International de l'Enseignement Technique has accepted an invitation from the Society of Arts, and certain of the City Guilds, to hold its meeting this year in London. The Congress will be opened on June 15.

PROF. C. CLAUS, Professor of Zoology at the Vienna University, has resigned; Dr. B. Hatschek, of Prague, has been made his successor in Vienna; and Prof. R. van Leudenfeld has been appointed to fill the chair of Zoology in the latter's place at Prague.

THE University of St. Andrews has conferred the honorary degree of LL.D. upon Mr. J. Scott Keltie, Secretary to the Geographical Society; Prof. H. S. Hele-Shaw, Professor of Engineering in University College, Liverpool; and the Rev. Alfred Merle Norman, F.R.S., Hon. Canon of Durham.

A MEETING will be held at Hugh Myddelton Board School, Clerkenwell, on Saturday next, April 3, at 3.30, to consider improvements in the methods of teaching domestic economy as commonly practised in schools. It will be proposed that in future the teaching should be of an exact nature, and such as to make the scholars think for themselves about the ordinary affairs of the household. For this end to be attained, simple but accurate experimental work dealing with domestic matters should be introduced into girls' schools. The Education Department have given their recognition to this view by introducing a new subject—domestic science—into the Code of Elementary Schools.

SCIENTIFIC SERIALS.

Bulletin of the American Mathematical Society, February.—Prof. A. W. Phillips contributes an obituary sketch of Prof. H. A. Newton, who died August 12, 1896. After pointing out, in some detail, his various lines of work, he closes thus:—"The achievements of Prof. Newton, great as they were from a scientific standpoint, give no adequate idea, taken in themselves, of his power and influence. He built up, during a leadership of forty years, a strong and symmetrical department of mathematics, by his comprehensive grasp of the trend of mathematical thought, and by his wonderful power of divining the paths which lead out to fruitful fields of research, both within the domain of pure mathematics and in its applications to other sciences. Nor was the first part of his academic activities merely in his own department of studies. In moulding the general policy of the institution, his counsel was invaluable; in establishing and maintaining the moral and intellectual standards, his influence was pre-eminent; the University bears the indelible impress of a life consecrated to the development of the noblest ideals."—Transcendental numbers is the translation, by Prof. W. W. Beman, of chapter xxv. of vol. ii. of Prof. H. Weber's Lehrbuch der Algebra. This is a fairly elementary presentation of the recent methods of demonstrating the transcendency of e and π. The sections treat of enumerable masses (a mass is said to be enumerable when its elements can be brought into a (1, 1) correspondence with the whole series of natural numbers, or a portion of the same), unenumerable masses, transcendency of e and of π, and Lindemann's general theorem regarding the exponential function.—Shorter notices are a review of Dr. Schwatt's geometrical treatment of curves which are isogonal conjugates to a straight line with respect to a triangle. Part i. (Boston, 1895), by Prof. F. Morley, of the annuaire pour l'An 1897, publié par le Bureau des Longitudes, by Prof. E. W. Brown.—Members of the Society resident in, or near, Chicago, held a mathematical conference at the University of Chicago on December 31, 1896, and January 1, 1897, and in future it is proposed to hold at least two similar meetings in the year, viz. during the Christmas vacation, and in the spring.—The titles of the papers read are given, with notes and new publications.

Wiedemann's Annalen der Physik und Chemie, No. 3.—Behaviour of quartz towards infra-red rays, by E. F. Nichols. This was investigated not by a bolometer or a thermo-element, but by a modified form of Crookes' radiometer, in which one of the vanes was screened and the other exposed to the rays reflected or transmitted by quartz. The rays, which were concentrated by a rock-salt lens and admitted to the radiometer through a fluorspar window, produced a torsion of the suspending quartz fibre, which was indicated by a mirror attached to the vanes. The reflection by quartz of light of the wave-length 7·4 μ is only 0·29 per cent. But at 8·45 μ it rivals that of burnished silver, 75 per cent. The transmission curve is very irregular, and beyond 8·1 μ no light is transmitted.—Heat rays of great wave-length, by H. Rubens and E. F. Nichols. Instead of using a grating or selective absorption for obtaining infra-red rays, the authors filtered them out by three successive reflections from surfaces of fluorspar or rock-salt, the source being a layer of the same substance on hot platinum foil. Heat rays of hitherto unrecorded length were thus obtained. The fluorite reflections gave waves of 24·5 μ, or over 30 times the length of the extreme red light waves. They are, reckoning by octaves, midway between the shortest ultra-violet waves and the shortest electrical waves (6 mm.) hitherto observed. Reflections from rock-salt gave waves of 50 μ.—Thermometer for very low temperatures, by F. Kohlrausch. Such a thermometer may be procured by the use of petroleum ether as the thermometric substance. It is very viscous but still sufficiently liquid at the temperature of boiling liquid air ($-190°$ C.), and shows a contraction of volume by as much as 25 per cent. from the ordinary to the lowest temperature. Amylene also remains liquid, but is more viscous.—Visibility of Röntgen rays, by G. Brandes and E. Dorn. When the vacuum tube is highly exhausted, the rays produce a sensation of light in most eyes, which is, however, difficult to localise. Most of the humours of the eye absorb the rays.—Interference surfaces at the kathode, and the electrostatic deflection of the kathode rays, by E. Wiedemann and G. C. Schmidt. The deflections of kathode rays observed by Jaumann are a secondary effect due to a modification of the field by the charged body, which produces a shifting of the origin of the rays on the kathode.—Demonstration of the course of variable currents, by F. Braun. A method by which the inertia of the indicator may be got rid of consists in making the current traverse an electro-magnet which deflects the kathode rays in a vacuum tube. The spot of light on a fluorescent screen vibrates, and the form of the vibration curve is studied by a revolving mirror.—Also papers by Dorn, Völlmer, Goldstein, Drude, König, Loomis, Voigt, and Glan.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 4.—"Luminosity and Photometry." By John Berry Haycraft, M.D., University College, Cardiff.

The luminosity of the spectrum was determined by the method of the "minimal effective stimulus," the portions of the spectrum investigated being as a physical quantity reduced in amount until its effect on the visual apparatus was just apparent. The luminosity was also determined by the "flickering" method. A rotating semi-disc periodically cut off the spectral ray, and produced flickering, which flickering disappeared after a certain speed of rotation had been reached: the speed of this rotation was taken as a measure of the luminosity. The curves obtained by these methods agreed with each other and with curves obtained by methods of "inspection" used by Abney and König. The curves obtained with the dark adapted eye—the observer was kept in a dark room during and for an hour before the experiment—gave a maximum in the green in the case of the minimal effective stimulus. With the light adapted eye—the room was whitewashed and lit by gas—the yellow of the spectrum was the most luminous. With the flicker method the curve of a spectrum of low physical luminosity has a maximum in the green, the curve of a spectrum of high luminosity in the yellow. Purkinje's phenomenon was also studied by the above methods, using coloured papers and a graduated gas-burner to vary the luminosity. The full paper will shortly appear in the *Journal of Physiology*.

Physical Society, March 26.—Mr. Shelford Bidwell, President, in the chair. At the invitation of Dr. S. P. Thompson, the meeting was held at the Technical College, Leonard Street, Finsbury. Mr. Rollo Appleyard read a paper on liquid coherers and mobile conductors, and showed the following experiments: (1) A glass tube, containing mercury and paraffin-oil, is shaken up until the mercury divides into small spheroids. The resistance of the chain of spheroids under these conditions is several megohms. Coherence can be brought about by a direct current, a spark, or by a Hertz oscillator. The coherence is visible, the spheroids forming into large globules. At the same time, the resistance falls to a fraction of an ohm. (2) An unstable emulsion is formed by shaking water and paraffin oil together, in a glass tube; called by the author a "rain" tube. The oil may be coloured with alkanet root. By electrification, the water suspended in the oil is suddenly precipitated in a shower through the oil, precisely as rain is precipitated in the air, after thunder. (3) A mixture of paraffin oil and water is poured into a photographic dish, just covering the bottom; and a little mercury is poured in. Any two separate globules of mercury in the dish are then connected by wires to a battery of about 200 volts, through a reversing-key. A momentary tap of the key causes instantaneous deformation of the mercury, especially of the globule connected to the negative pole. If the current is kept on, the negative globule sends forth a long tentacle of mercury across the dish to the positive globule. The tentacle may break into spheroids. Intermediate globules send forth "fingers" towards the positive terminal globule; and, by continued application of the current, the "fingers" link intermediate globules; illustrating the nature of liquid coherence. By using the current-reverser as a telegraphic transmitting-key, the motions, to right or left, of the "finger" of any stray globule may be interpreted to form the letters of the Morse code. By a succession of taps of the key in one direction or the other, a globule can be made to "caterpillar" along the dish. Prof. Ramsay said he had once attempted to facilitate churning by the application of 8 or 9 volts to some milk. He thought the cream came a little faster, but it turned sour very quickly. Prof. Fitzgerald thought that the effects observed in experiment (3) were the result of current, and not of electro-static changes, and he would like to know the value of the actual current used. There was no doubt that the motions were due to variations in capillarity. Mr. Shelford Bidwell asked how the mercury was formed into spheroids in the tube in experiment (1). Mr. Appleyard, in replying to Prof. Fitzgerald, said it was not easy to define the circuit, as the terminal-globules were rather capricious, but he would try and measure the current in some particular case. The mercury-tube in experiment (1) was shaken in a horizontal plane; the operation took about ten minutes. Equal volumes of mercury and oil was a good proportion. One-quarter of the length of the tube should be left as an air-space.—Prof. Dalby then exhibited five pieces of apparatus: (1) a kinematic slide, (2) an inertia apparatus with trifilar suspension, (3) a Wilberforce spring, (4) an Ewing's reading-telescope, (5) a kinematic Hook-gauge. Models (1), (2), (4), and (5) illustrated the various degrees of freedom of bodies restrained at different numbers of points. It was shown with (3), that in extending a spiral spring there results a certain amount of twisting. If a mass is hung at the lower end of the spiral in such a way that, when suddenly released after extension of the spring, the time of oscillation of the mass in the horizontal plane (rotation) is the same as the time of vertical oscillation, then the tendency to twist results in a change of energy which alternates between the rotary and linear forms. Mr. Boys drew attention to the conditions of restraint, and suggested a criterion for determining whether a piece of mechanism was designed for minimum strain on the structure: a thin wedge slipped under any one point of contact should not disturb the other points of restraint. Prof. Fitzgerald pointed out the effect of symmetry upon the motion of the spring of (5). The spiral happened to be an unsymmetrical form; the change of phase from vertical to rotary oscillation was therefore rapid. In the case of the vibration of a symmetrical stretched cord the change of phase would be very slow.—Dr. Thompson exhibited two kinematic models depending upon the principle that any simple harmonic motion may be considered as the resultant of two oppositely-directed motions. The first illustrates the synthesis of two opposite circular motions of equal period and amplitude to form a straight-line motion; the second shows the combination of two simple harmonic motions of equal period and amplitude in any difference of phase, to form a circular motion. In each case the motion is communicated to a stylus by a link-gear, operated by two wheels rotating in opposite directions. In the first apparatus, the wheels are pivoted about their centres, and the link-gear is pinned to one point on the flat surface of each wheel, near the circumference; in the second apparatus, the wheels rotate as eccentrics at 180° to one another, and the motion to the link-gear is communicated by thrust-rods, held by springs against the peripheries of the corresponding wheels. Dr. Thompson further exhibited a device for projecting, by lantern, the rotating magnet and copper disc, of Arago. The curious rotations and lateral movements of iron-filings, in a revolving magnetic field, were similarly projected on a screen. He also showed some experiments with a heat-indicating paint, made from a double iodide of copper and mercury, discovered twenty years ago by a German physicist. At ordinary temperatures the paint is red, but at 97° C. it turns black. If paper is covered with this substance, and then warmed at a stove, the change is effected in a few seconds. Various designs can be wrought upon the back of the paper in dead-black or gold, so that when warmed they appear in red or black on the front, according to their respective absorptive powers. Or local cooling by the hand will yield a silhouette. If the paper is allowed to cool, the silhouette vanishes, but it appears again when the paper is reheated. It has thus a kind of thermal "memory." A yellow double iodide of silver and mercury is even more sensitive. It changes from yellow to dark red at 45° C. Lastly, Dr. Thompson exhibited a kinematic model of Hertz-wave transmission. A row of lead bullets is suspended from strings, so that the bullets hang clear of one another by about an inch, in a right line. The strings are meshed, and herein the model differs from the well-known wave-models used in acoustics. If the attempt is made to send an acoustic form of wave through the system, by giving an impulse to the first bullet in the plane of the other pendulums, it fails immediately, owing to the slackening of parts of the meshes. Thus, only *transverse* vibrations can be transmitted. To illustrate the propagation of a Hertz-wave, a heavy pendulum, oscillating in a plane at right-angles to the line of bullets at one end, represents the Hertz "oscillator." A metal ring, mounted horizontally on a trifilar suspension, and properly "tuned," represents, at the distant end, the Hertz "resonator." Waves, formed by the transverse vibrations of successive bullets, are then propagated from end to end. Prof. Fitzgerald said the model was specially interesting as illustrating the difference in velocities of propagation of a given wave, and of the energy corresponding to it. The model did not accurately compare with ether, because in ether the rate at which the energy is propagated is the same as that of the wave. The difference of the two rates, for any medium, depended upon the "dispersion"

of the medium. By slight alteration of the pendulum-suspensions this dispersion might be made different at different parts of the model, and would then correspond to certain known cases of "anomalous dispersion." Or, again, it might be made to illustrate the theory of Helmholtz with regard to the vibrations of the molecules of glass; according to which, the vibration of the molecules alters the vibrations of the waves, so that dispersion occurs, and the energy is not propagated at the same rate as the waves themselves. It was shown by Michaelson that it was possible to have a medium in which the energy is propagated in one direction, and the wave in another. This was attained, in a magnetic model, by Ewing. The mesh apparatus indicated how a model could be made which should give out "harmonics" and "over-tones" very different from one another; where different wave-lengths would be propagated with different velocities, and the over-tones would correspond to the differences Further, it indicated a mechanism for producing any desired spectrum; such, for instance, as that of hydrogen. A somewhat similar model had been designed by Glazebrook for illustrating the absorption-bands of a medium when the rate of vibration was the same as the free period of the vibrations of each of the molecules, which is the theory of Helmholtz, but it was not such a simple model. The experiment of red paper changing to black was interesting as illustrating a red spectrum varying with temperature.—Mr. Shelford Bidwell proposed votes of thanks to all the exhibitors, and the Society adjourned until April 9.

Chemical Society, March 18.—Mr. A. G. Vernon Harcourt, President, in the chair.—The following papers were read:—On the atomic weight of carbon, by A. Scott. The author calls attention to the unsatisfactory nature of the experimental evidence on which the determinations of the atomic weight of carbon rest; erroneous determinations of the expansion produced by the absorption of carbon dioxide by potash solutions have been employed. When this and other sources of error have been allowed for, the recalculated values of the atomic weight of carbon are 12·008 from the combustion of carbon and 12·050 from the conversion of the monoxide into the dioxide.—On a new series of mixed sulphates of the vitriol group, by A. Scott. The author obtains members of a new series of mixed sulphates of the composition $(MN)'SO_4.H_2O$ by adding sulphuric acid to solutions of the mixed sulphates; the ferrous cupric salt $Cu_2Fe_5(SO_4)_7, 7H_2O$ is reddish-brown in colour.—A synthesis of camphoronic acid, by W. H. Perkin, jun., and J. F. Thorpe. Ethylic β-hydroxy-αα'β-trimethylglutarate is converted by the usual methods into ethylic β-cyano-αα'β-trimethylglutarate, $COOEt.CMe_2.CMe(CN).CH_2.COOEt$; this on hydrolysis yields αα'β-trimethyltricarballylic acid, $COOH.CH_2.C(COOH)Me.CMe_2.COOH$, which is found to be identical with camphoronic acid.—Note on a method of determining melting points, by E. H. Cook.—Velocity of urea formation in aqueous alcohol, by J. Walker and S. A. Kay. The addition of ethylic alcohol to an aqueous solution of ammonium cyanate undergoing conversion into urea accelerates the reaction; if the reverse action and the degree of dissociation at the various stages of the process are taken into consideration, it is found that the law of mass-action is strictly obeyed. The authors calculate that the conversion of ammonium and cyanate ions into urea is accompanied by a heat evolution of about 5000 cals. per gram-molecule.—Action of alkyl haloids on aldoximes and ketoximes, by W. R. Dunstan and E. Goulding. When formaldoxime, acetaldoxime, and acetoxime are heated with an alkyl iodide or bromide in alcoholic solution, compounds of the types $R'CHN(R')O$ and $R'_2CNCH(R')O$ are obtained.

Entomological Society, March 17.—Mr. Roland Trimen, F.R.S., President, in the chair.—Mr. Butterfield, present as a visitor, exhibited a series of thirty-three male and six female *Phigalia pedaria*, taken near Bradford, Yorkshire, on February 14–17, 1897. Twenty-one males were typical in having a greater or less development of the four transverse bars. The remaining twelve were without bands, and varied in colour from black to smoky olive; they were decidedly less in point of size, ranging from 1 1/8 in. to 1 1/2 in., as against 1 1/2 in. to 1 1/2 in. in the banded forms, and were also poorer in scales and slightly deformed. He had only met with this variety once before in the last twenty years, and suggested that the eruption of small, black, and depauperised forms might have been produced by dryness and want of food in the larval conditions, the trees having been extensively defoliated in the preceding year.—Mr. Kirkaldy exhibited an example of the rare macropterous form of *Velia currens*, Fabr., taken at East Grinstead, and one of *Cicadetta montana*, Scop., from Brockenhurst.—Mr. Burr exhibited a series of grasshoppers with red and blue hind wings, of the family Œdipodidæ, to show the remarkable variation in colour seen in this group. Red, blue, and yellow forms are found alike in the same species, the blue being due to the failure of the red pigment, and therefore an incipient albinism, the yellow being a further form of albinism.—Mr. Champion communicated a paper on the Elateridæ and Rhipidoceridæ collected by Mr. H. H. Smith at St. Vincent, Grenada, and the Grenadines, and exhibited the specimens.—Dr. Forel also communicated a paper on the Formicidæ collected by Mr. Smith in the same islands.

Linnean Society, March 18.—Dr. A. Günther, F.R.S., President, in the chair.—Mr. Bernard Arnold exhibited three contiguously-built nests of the chimney swallow, *Hirundo rustica*, having a continuous wall of mud as if built by one pair of birds; but from the evidence of the observer it appeared that there were two pairs of birds, and that one pair had made two of the adjacent nests.—The Right Hon. Sir John Lubbock, Bart., F.R.S., read a paper on stipules, their forms and functions. This embodied observations supplementary to those published in previous papers (*Linn. Soc. Journ., Bot.* xxviii. 217, and xxx. 463). It was shown that while the usual function of stipules is to protect leaves in bud, in some cases they replace them, and in others serve to hold water. Instances were mentioned in which stipules developed into spines, and in other cases became glandular. Where stipules were absent, other arrangements for bud protection were found to exist. Attention was especially directed to the formation of the winter buds of certain common shrubs and trees, and some curious differences were noted even in nearly allied species. In the wayfaring-tree, *Viburnum Lantana*, the author remarked that the young leaves are uncovered, but are protected by a growth of hairs; in the ash and thorn the outer scales of the bud consist of expanded petioles; in the willow the outer scales consist of leaves; in the poplar of stipules. The buds of the oak and beech were also described; and it was shown by the aid of lantern-slides that in the beech the outer scales of the bud consist of two pairs of stipules, that the twelfth pair are the first which have a leaf, and that the subsequent growth is between the leaves, while the portion of the shoot between the stipules scarcely elongates at all. As a consequence the seat of each winter bud is marked by a ring, and thus a series of successive rings which remain visible for many years indicate each year's growth.—Mr. W. C. Worsdell read a paper on the origin of transfusion-tissue in leaves of gymnospermous plants. It was explained that "transfusion-tissue" is a special kind of conducting-tissue found chiefly in the leaves of conifers, in direct connection with the vascular bundles. Evidence was adduced in favour of the conclusion that transfusion-tissue, as universally found in recent coniferous leaves, has originally sprung from the centripetal xylem of the leaf-bundle of the ancestors of these plants.

CAMBRIDGE.

Philosophical Society, March 8.—Mr. F. Darwin, President, in the chair.—On the injection of the intercellular spaces occurring in the leaves of *Elodea* during recovery from plasmolysis, by the President and Miss D. F. M. Pertz. *Elodea* continues to assimilate in salt solutions strong enough to plasmolyse the cells. On replacing the plant in water assimilation ceases, the gas disappears from the intercellular spaces, and the leaf is injected with water. The disappearance takes place partly by the escape of bubbles at the open ends of the intercellular spaces, but chiefly by solution. The first of these phenomena depends on the surface tension of salt solutions being greater than that of water. The solution depends on the fact that air is less soluble in salt solutions than in water.—The phenomena of carbon dioxide production associated with reduced vitality in plants, by Mr. F. F. Blackman. By the aid of an apparatus (which was exhibited), specially adapted for physiological research on very small outputs of carbon dioxide, several new phenomena of this nature have been brought to light in plants. These comprise the liberation of carbon dioxide produced in the following four cases. Firstly, that resulting from the action of temperatures between 40° C. and 50° C. on dry resting seeds: at temperatures below 40° C. no appreciable

formation of carbon dioxide takes place, and at continued higher temperatures the amount, which is at first large, does not remain so but steadily falls off, indicating the decomposition of a definite limited quantity of some substance. Secondly, the large amount of carbon dioxide produced in the first few hours after wetting coarsely-ground dry seeds. This cannot be attributed to the action of micro-organisms, and is hindered by the action of chloroform and other poisons. Thirdly, the varying production of carbon dioxide by the action of volatile poisons and of fatal temperatures on living leaves. Finally, the post-mortem production of carbon dioxide brought about by subjecting recently-killed leaves to the action of a temperature of 100° C. This amount was shown to vary with the method of killing adopted, and evidence was forthcoming to show that in this, as in the other cases, those substances which easily oxidise with liberation of carbon dioxide are in some way to be associated with normal respiratory processes.—On the leaves of *Bennettites*, by A. C. Seward. In this paper the author described some specimens of *Williamsonia gigas* Carr. and *Zamites gigas* L. and H., from the Jurassic rocks of the Yorkshire coast, and now in the Natural History Museum, Paris. In recent years it has been customary to discredit or entirely deny the correctness of the earlier views as to the generic identity of *Zamites gigas* and *Williamsonia*. A recent examination of the specimens in the Paris Museum convinced the author that *Williamsonia* is the inflorescence of *Zamites gigas*. The conclusions now arrived at enable a Bennettitean inflorescence to be connected with a definite form of fronds.

PARIS.

Academy of Sciences, March 22.—M. A. Chatin in the chair.—The President announced to the Academy the loss it had sustained by the death of M. Antoine d'Abbadie, Member of the Section of Geography and Navigation.—On the Phanerogams without seeds, forming the division of the Insemineæ, by M. Ph. van Tieghem. An outline of a new classification of the Phanerogams.—On the mechanical work performed by muscles, by M. A. Chauveau. An extension of a preceding paper, giving details of experiments with isolated fresh muscles from frogs. The muscle was weighted with different loads, stimulated with a rapidly alternating current, and the heating effects produced measured with a thermo-electric couple.—On an angular multi-divider, by M. Guillerminet.—On an electric commutator capable of being adjusted from a distance, by M. C. Gros.—On the perihelia of the planets, by M. Delauney.—On autoradioscopy, by M. Foveau de Courmelle.—On the geometry of the triangle, by M. Labergère.—On the successive differentials of a function of several variables, by M. Moutard.—On the determination of the group of transformations of a linear differential equation, by M. F. Marotte.—On the latent heats of evaporation and the law of Van der Waals, by M. Georges Darzens. The author has shown in a preceding note that the Van der Waals equation $M\lambda/T_c = f(T/T_c)$ (where M is the molecular weight, λ the latent heat of vaporisation at the absolute temperature T, and T_c the absolute critical temperature) may be put in the form $M\lambda/T = F(T/T_c)$, where the first term is independent of the critical temperature. The exactness of the law of corresponding states may be indirectly verified by plotting on squared paper the values of $M\lambda/T$ as ordinates against T/T_c as abscissæ, and seeing if the resulting points, either for one substance at different temperatures, or for different substances, lie on a continuous curve. It was found necessary to divide the substances taken into groups in order to get the points to lie on a curve. Thus benzene, chloroform, carbon tetrachloride, sulphur dioxide, nitrous oxide, and carbon dioxide form one group; water, acetone, and ether form another.—Stereoscopy of precision applied to radiography, by MM. T. Marie and H. Ribaut. The theoretical development of the subject is first given, and then measurements from a series of experiments bearing out the results of the preceding analysis.—The action of nickel upon ethylene, by MM. Paul Sabatier and J. B. Senderens. The nickel used in these experiments was reduced by hydrogen from the oxide at as low a temperature as possible; as it was found that this metal gave the most rapid reaction. The property of acting upon ethylene, however, is not lost even if the nickel oxide is reduced at a red heat. The reaction between the nickel and the ethylene takes place at about 300°; and the main reaction appears to be according to the equation $C_2H_4 = C + CH_4$, although hydrogen is also produced by what is apparently a secondary reaction, the amount increasing with the temperature of the nickel. No such phenomenon occurs when the nickel is replaced by copper, cobalt, iron, or by platinum or palladium black.—Researches on the monazite sands, by MM. G. Urbain and E. Budischovsky. The hydrated earths were treated with acetylacetone, and the resulting acetylacetonates fractionally recrystallised from alcohol and benzene. The lowest atomic weight obtained from the fractions was 95, the highest 112.—A reaction of carbon monoxide, by M. A. Mermet. A solution of potassium permanganate, acidified with nitric acid, and containing silver nitrate, is decolorised by carbon monoxide. With air containing ·002 to ·0002 of its volume of carbon monoxide, the decolorisation was complete in from one to twenty-four hours. Upon this reaction is based the determination of small quantities of CO in rooms.—On isolauronolic acid, by M. G. Blanc. Isolauronyl chloride, treated with zinc methyl in ethereal solution, yields an isomer of camphor, of which the oxime, semicarbazone, hydrazone, and reduction products are described.—On a new method of storing acetylene, by MM. Georges Claude and Albert Hess. It has been found that acetone is a good solvent for acetylene, one kilogram of acetone dissolving 300 litres of acetylene under a pressure of 12 atmospheres.—On the mineralogical constitution of the island of Polycandros, by M. A. Lacroix. The south-eastern portion of the island consists of white or greyish-white limestone deposits, the remainder consisting of mica and chlorite schists.—On the part played by phenomena of superficial alteration in metalliferous strata, by M. L. de Launay.—On the gradual loss of lime in basic eruptive rocks of the region of the Pelvoux, by M. P. Termier.—Work carried out by the Geographical Service of the Expeditionary Corps of Madagascar, during the campaign of 1895, by M. R. Bourgeois.—The movement of lunar rotation, by M. D. A. Casalonga.—On an apparatus called a kineometer, by M. Aug. Coret.—The problem of aviation, by M. Th. Colombier.

AMSTERDAM.

Royal Academy of Sciences, January 30.—Prof. van de Sande Bakhuyzen in the chair.—Prof. Engelmann, referring to experiments made by Dr. Woltering and himself at Utrecht, treated of the rate at which stimuli of various intensity are propagated through muscular fibres.—Prof. van Bemmelen made a communication concerning the chemical metamorphosis of phosphate in fossil bones.—Prof. van der Waals described an inquiry made by himself, in accordance with the molecular theory of a mixture developed by the author (*Arch. Neerl.*, t. xxiv.), into the extent to which the complexity of the molecules of a solvent may influence the magnitude of the decrease of vapour-tension by dissolved salts. He arrived at the conclusion that the decrease of vapour-tension is determined solely by the magnitude of the molecules of the solvent when in the state of vapour.—Prof. Engelmann presented, on behalf of Mr. E. G. A. ten Siethoff, of Deventer, a paper entitled "An explanation of the optical phenomenon in the eye, discovered by Dr. P. Zeeman." Dr. Zeeman described (Report of the meeting of the Physical Section of the Royal Acad. of Sc., February 25, 1893; NATURE, vol. xlvii., 1893, p. 504; and *Zeitschr. f. Psych. und Phys. d. Sinnesorg*, vol. vi., 1894, p. 233-234) a subjective optical phenomenon, which occurs when a slit, brightly illumined, preferably by monochromatic yellow light, is observed in the dark. Then a bluish-violet line of light is seen, curved like the outline of a pear, whose axis stands perpendicularly upon the middle of the slit. When regarded with the right eye, the point of the light figure is turned to the right (to the left when seen with the left eye), and the rounded side slightly overlaps the illumined slit. The observation of the phenomenon is easiest with yellow or white light; still, Dr. Zeeman succeeded in observing it when using any of the three hydrogen lines. The subjective optical phenomenon observed by Dr. Zeeman ought, in the author's opinion, to be conceived as an entoptical, complementary after-image of the macula lutea and its surroundings, caused by the percipient elements posterior to it being stimulated. This after-image is violet-coloured with any kind of light, because in the place indicated yellow light always prevails, in consequence of the elective absorption of the yellow pigment.—Prof. Kamerlingh Onnes read a letter from Mr. Edm. van Aubel, of Brussels, concerning the experiments of Dr. Zeeman, mentioned at a previous meeting, "On the influence of magnetism on the nature of the light emitted by a substance."

DIARY OF SOCIETIES.

THURSDAY, APRIL 1.

ROYAL SOCIETY, at 4.30.—The Croonian Lecture—"The Mammalian Spinal Cord as an Organ of Reflex Action"—will be delivered by Prof. C. S. Sherrington, F.R.S.

ROYAL INSTITUTION, at 3.—The Relation of Geology to History: Prof. W. Boyd Dawkins, F.R.S.

SOCIETY OF ARTS, at 4.30.—A Visit to Russian Central Asia: Michael Francis O'Dwyer.

LINNEAN SOCIETY, at 8.—On the Evolution of Oxygen from Coloured Bacteria: Dr. A. J. Ewart.—On the Germination of Spores of Agaricineæ: Miss Helen Beatrix Potter.

CHEMICAL SOCIETY, at 8.—On the Oxidation of αγ-Dimethyl-α'-Chloropyridine: E. Aston and Prof. J. Norman Collie, F.R.S.—The Composition of Cooked Fish: K. J. Williams.

CAMERA CLUB, at 8.15.—Mountain and West Coast Scenery at Home and Abroad: T. C. Porter.

FRIDAY, APRIL 2.

ROYAL INSTITUTION, at 9.—Metallic Alloys and the Theory of Solution: Charles T. Heycock, F.R.S.

GEOLOGISTS' ASSOCIATION, at 8.—The Physical History of Romney Marsh: George Dowker.—A Collection of Flint Implements from Cookham: Llewellyn Treacher.

SATURDAY, APRIL 3.

ROYAL INSTITUTION, at 3.—Electricity and Electrical Vibrations: Lord Rayleigh, F.R.S.

GEOLOGISTS' ASSOCIATION (Baker Street Station), at 1.37.—Excursion to Chesham and Cowcroft. Director: Upfield Green.

MONDAY, APRIL 5.

SOCIETY OF ARTS, at 4.30.—Alloys: Prof. W. C. Roberts-Austen, C.B., F.R.S.

SANITARY INSTITUTE, at 8.—Sanitary Building Construction: Prof. T. Roger Smith.

SOCIETY OF CHEMICAL INDUSTRY, at 8.—Election of Officers and Five Members of Committee for the Session 1897-98.—The Chemical Stability of Nitro-compound Explosives: Oscar Guttmann.

VICTORIA INSTITUTE, at 4.30.—Australian Aboriginal Art: The Bishop of Ballarat.

TUESDAY, APRIL 6.

ROYAL INSTITUTION, at 3.—Animal Electricity: Prof. A. D. Waller, F.R.S.

SOCIETY OF ARTS, at 8.—Recent Travels in Rhodesia and British Bechuanaland: C. E. Fripp.

ZOOLOGICAL SOCIETY, at 8.30.—On the Myology of the Terrestrial Carnivora: Drs. B. C. A. Windle and F. G. Parsons.—Note upon the Minute Structure of the Teeth of *Notoryctes*: C. S. Tomes, F.R.S.—On the Blue Bear of Tibet, with Notes on the Members of the *Ursus arctus* Group: R. Lydekker, F.R.S.—An Account of the Freshwater Fishes collected in Celebes by Drs. P. and F. Sarasin: G. A. Boulenger, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Paper to be further discussed: Electric Lifts and Cranes: Henry W. Ravenshaw.—Paper to be read, time permitting: The Blackwall Tunnel: David Hay and Maurice Fitzmaurice.—Ballot for Members.

MINERALOGICAL SOCIETY, at 8.—On a New Occurrence of Apophyllite in South Africa: J. Henderson.—On a Mineral from Hungary: Messrs. Prior and Spencer.—On the Indexing of Mineralogical Literature: Prof. Miers.—Some Simple Names for the Thirty-two Types of Crystal Symmetry: Prof. Miers.

ROYAL VICTORIA HALL, at 8.30.—Movements of Plants: Rev. George Henslow.

WEDNESDAY, APRIL 7.

SOCIETY OF ARTS, at 8.—Dairy Produce and Milk Supply: M. J. Dunstan.

GEOLOGICAL SOCIETY, at 8.—On the Morte Slates and Associated Beds in North Devon and West Somerset, Part II.: Dr. Henry Hicks, F.R.S.—The Glacio-Marine Drift of the Vale of Clwyd: T. Mellard Reade.

ENTOMOLOGICAL SOCIETY, at 8.—Report of the Committee on the Protection of British Insects in danger of Extermination.

SANITARY INSTITUTE, at 8.—Notification of Measles: Dr. Henry R. Kenwood.

SOCIETY OF PUBLIC ANALYSTS, at 8.—The Separation and Identification of the Typhoid and Colon Bacilli: F. Wallis Stoddart.—Notes on Alcohol: J. F. Liverseege.

INSTITUTION OF NAVAL ARCHITECTS, at 12.—Annual Report of Council, Election of President, Officers, and Council.—Address by the Chairman, the Right Hon. the Earl of Hopetoun, G.C.M.G.—The following Papers will then be read and discussed:—Recent Trials of the Cruisers *Powerful* and *Terrible*: A. J. Durston, C.B., R.N.—Water Tube Boilers in Warships: Rear-Admiral C. C. P. Fitzgerald, R.N.—A Mechanical Method of ascertaining the Stability of Ships: A. G. Ramage.

THURSDAY, APRIL 8.

ROYAL SOCIETY, at 4.30.—*Probable* Papers: The Production of X-rays of different Penetrative Values: A. A. C. Swinton.—On the Application of Harmonic Analysis to the Dynamical Theory of the Tides, Part I.: S. S. Hough.—Photographic Spectra of Stars to the 3¼ Magnitude: F. McClean, F.R.S.—(1) Double (Antidrome) Conduction in the Central Nervous System; (2) Further Note on the Sensory Nerves of Muscles: Prof. Sherrington, F.R.S.—On the Breaking-up of Fat in the Alimentary Canal under Normal Circumstances and in the Absence of the Pancreas: Prof. V. Harley.—Condensation of Water Vapour in the Presence of Dust-free Air and other Gases: C. T. R. Wilson.—On Boomerangs: G. T. Walker.

ROYAL INSTITUTION, at 3.—Roman Britain: Prof. W. Boyd Dawkins, F.R.S.

MATHEMATICAL SOCIETY, at 8.—On the Potentials of Rings: A. L. Dixon.—An Extension of a certain Theorem: Rev. F. H. Jackson.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Recent Developments in Electric Traction Appliances: H. A. Baylor.

INSTITUTION OF NAVAL ARCHITECTS, at 12.—On the Fighting Value of certain of the Older Ironclads if re-armed: Captain the Right Hon. Lord Charles Beresford, C.B., R.N.—The Application of the Compound Steam Turbine to the Purpose of Marine Propulsion: Hon. Charles Parsons.—On the Use of the Mean Water-Line in designing the Lines of Ships: A. G. Ramage.——At 7.—The Accelerity Diagram of the Steam-Engine: J. Macfarlane Gray.—Note on the Geometry of Stability: J. Macfarlane Gray.—Acetylene, and its Probable Future Afloat: Prof. Vivian B. Lewes.

CAMERA CLUB, at 8.15.—The Phonograph: Mr. Stroh and F. C. B. Cole.

FRIDAY, APRIL 9

ROYAL INSTITUTION, at 9.—The Limits of Audition: Lord Rayleigh, F.R.S.

PHYSICAL SOCIETY, at 5.—A Nickel Stress Telephone: T. A. Garrett and W. Lucas.—On Alternating Currents in Concentric Conductors: W. A. Price.—On the Effect of Capacity on Stationary Electrical Waves in Wires: W. B. Morton.

ROYAL ASTRONOMICAL SOCIETY, at 8.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Poole Harbour: Harold Berridge.

BOOKS, PAMPHLETS, and SERIALS RECEIVED.

BOOKS.—First Stage Inorganic Chemistry: Dr. G. H. Bailey (Clive).—Statesman's Year Book, 1897 (Macmillan).—Algebra for Beginners: Dr. I. Todhunter, revised and enlarged by Prof. S. L. Loney (Macmillan).—Hydraulic Machinery: R. G. Blaine (Spon).—Bourne's Insurance Directory, 1897: W. Schooling (E. Wilson).—Report of Observations of Injurious Insects: E. A. Ormerod, 20th Report (Simpkin).—Who's Who, 1897 (Black).—Les Femmes dans la Science: A. Rebière, deux édition (Paris, Nony).—Among British Birds in their Nesting Haunts: O. A. J. Lee, Part 3 (Edinburgh, Douglas).—First Principles of Natural Philosophy: Prof. A. E. Dolbear (Boston, Mass., Ginn).—Natural History in Shakespeare's Time: H. W. Seager (Stock).—Recherches sur la Sève Ascendante: H. S. Chamberlain (Neuchatel, Attinger).—Ueber den Bau der Kralleniffe: Dr. A. Krämer (Kiel, Lipsius).—Congrès International des Pêches Maritimes, September 1896, Comptes rendus des Séances (Paris).—A Guide to the Clinical Examination of the Blood for Diagnostic Purposes: Dr. R. C. Cabot (Longmans).

PAMPHLETS.—On the Colour and Colour-Patterns of Moths and Butterflies: A. G. Mayer (Boston, Mass.)—Some Factors in the Evolution of Adaptations: J. D. Haviland (Porter).—Birds of the Galapagos Archipelago: R. Ridgway (Washington).

SERIALS.—Longman's Magazine, April (Longmans).—Good Words, April (Isbister).—Sunday Magazine, April (Isbister).—Chambers's Journal, April (Chambers).—Religuary, &c., April (Bemrose) —Journal of the Chemical Society, February (Gurney).—Economic Journal, March (Macmillan).—Century Magazine, April (Macmillan).—Zeitschrift für Criminal-Anthropologie, Band 1, Heft 1 (Berlin, Priber).—Himmel und Erde, Marz (Berlin, Paetel).

HEAT (AND OTHER MATTERS).

Die Principien der Wärmelehre, historisch-kritisch entwickelt. Von Prof. E. Mach. Pp. viii + 472. (Leipzig : J. A. Barth, 1896.)

PROF. MACH has conceived this treatise in much the same spirit as his "Mechanik." Both books are partly based upon his lectures : neither of them pretends to give a complete account of the subject in its details and applications. The aim is rather to describe the principal facts and the development of ideas, to explain their connection and to examine critically the principles which underlie the study of thermal phenomena.

The contents of the book may be roughly divided into three parts, of which the first two deal with heat and thermodynamics. In these the general arrangement is a compromise between the strictly historical method and that of the ordinary text-book ; nowhere is any attempt made to secure the completeness and detail of a technical treatise. Subjects which have been fully discussed by other authors (such as thermo-chemistry and the dynamical theory of gases) are omitted, or only briefly referred to. In the first part the principal subjects treated of are thermometry, the conduction of heat, radiation, calorimetry and the calorimetric properties of gases. In each case there is a historical survey, followed by a critical discussion of the ideas involved in the development of the subject. The chapters on thermometry open in quite the orthodox way. We meet our old friends the three basins of water—cold, lukewarm and hot—and are warned of the danger of relying implicitly upon the uncontrolled verdict of our senses. In the next chapter (a critique of the idea of temperature) we are further warned that we have nothing to do with metaphysical ideas as to a "true" or "natural" scale of temperatures ; the object of thermometry being to indicate the thermal state of a body by a number with reference to a scale which can be produced and reproduced with certainty and accuracy. Every distinct pyrometric method involves a different definition of temperature ; and the temperatures measured by any one of these methods have just the same significance as numbers in an inventory. We now come to two chapters which give us a foretaste of the freedom of treatment in which the author indulges so fully in the last third of the book. In one of these he answers the questions, "What are numbers?" and "What are names?" ; the other is devoted to a discussion of *Das Continuum*. We next follow the slow growth of quantitative conceptions as to the conduction of heat, beginning with the case of a bar heated at one end. First we have Amontons' incorrect assumption that the temperature increases proportionately to the distance from the cold end. Lambert has a clearer conception of the permanent state, and finds that the excess of temperature above that of the surrounding medium follows an exponential law : but the way in which he deduces the result is incorrect. Biot, making use of Newton's law of cooling, first gives a correct theoretical and experimental investigation of this case. The more general treatment of conduction is due to Fourier, whose "Théorie analytique de la Chaleur" has been of the greatest importance in the development and transformation of the methods of mathematical physics. Considered from the physical standpoint, Fourier's theory has the merit of not being based (as is the kinetic theory of gases) upon an hypothesis, but upon an assumption proved by experiment to be correct, viz. that the flow of heat is proportional to the rate of change of temperature along the line of flow. His mathematical treatment is highly original and exquisite in form. At the same time his work well illustrates the beneficial reaction of investigations in various branches of physics and mathematics. The way for Fourier had been prepared by the researches of Taylor and others on the vibrations of stretched strings and the nature of partial differential equations (the results of which are here reproduced in somewhat modernised form). In turn, the powerful methods which he devised for solving problems on the conduction and radiation of heat have proved invaluable in the study of electricity, diffusion and hydrodynamics.

Among the founders of thermodynamics, Sadi Carnot occupies an unique position—one which must be rather unintelligible to those who hold that this science owes its birth to the conception of heat as a "mode of motion." In 1798 Rumford published his "Inquiry," and came to the conclusion that heat "cannot possibly be a material substance." Soon afterwards Davy, from further experiments, had deduced that "heat . . . may be defined a peculiar motion. . . ." And long before these two experimenters there had been speculations to the same effect. Yet Carnot's "Réflexions sur la puissance motrice du feu" (1824) throughout assumes the materiality (or indestructibility) of heat. In his *Gedankenexperiment*, the reversible cycle, it is assumed that the heat lost by the working substance in one set of operations is precisely compensated by the amount absorbed in the other set. "Ce fait n'a jamais été révoqué en doute. . . . Le nier, ce serait renverser toute la théorie de la chaleur." In spite of this, of the incorrect definition of the third operation in the cycle, of the difficulty of accepting step by step his reasoning, his conclusions are correct, and his method has proved profoundly suggestive. How happy his choice of the reversible cycle was, we can only appreciate by considering the very imperfect state of knowledge at that time as to the thermal properties of bodies : by requiring that the working substance should finally be brought back to its primitive physical condition, he ensures that it shall contain the same amount of heat after the cycle as before, and thus skilfully avoids a gap which could not then be bridged. In 1834 Clapeyron recalled attention to Carnot's essay, and gave appropriate graphical and analytical expositions of his method ; but he still adheres to the hypothesis of the invariability of the quantity of heat (gained and lost in the cycle), and does not advance the essential ideas beyond the stage in which Carnot left them. These ideas first fell upon good ground in our own country, and bore fruit in Thomson's remarkable paper, "On an Absolute Thermometric Scale," published in 1848.

In one respect fate did not deal kindly with Carnot. He admits (in words following those quoted above) that the foundations on which the theory of heat rests require careful examination, and that several experi-

mental facts appear nearly inexplicable in the actual state of this theory; nevertheless, if we had only the "Réflexions" to guide us, we should have to regard him as an adherent of the caloric hypothesis. Carnot died of cholera in 1832, and some forty years elapsed before the publication of his note-book showed how his views had changed since 1824. We have only space for one extract.

"On peut donc poser en thèse générale que la puissance motrice est en quantité invariable dans la nature, qu'elle n'est jamais, à proprement parler, ni produite, ni detruite. A la vérité, elle change de forme, c'est-à-dire qu'elle produit tantôt un genre de mouvement, tantôt un autre; mais elle n'est jamais anéantie."

Then follows an estimate of the number of units of heat required for "la production d'une unité de puissance motrice"! One cannot help wondering what might have happened if he had lived a few years longer, or if his views had not remained so long hidden.

As it is, the subsequent development of thermodynamics has not been the work of one person or of one country. The chapters in which Prof. Mach traces its growth, are amongst the most interesting in the book. One of his titles—"Das Mayer-Joule'sche Princip"—recalls a controversy the echoes of which have not yet died away, and indicates his position with reference to it. That position is one which many of our countrymen will not willingly accept; any more than they would accept the statement made on p. 261—"Im Grunde ist der Weg, auf dem Joule zu seiner Entdeckung gelangt, sehr ähnlich demjenigen Mayer's." But it would be unfair to allow such brief quotations to lead to the inference that the author is unfair or influenced by national bias. On the same page he draws attention to the soundness of Joule's scientific method; points out that he never befogged himself with metaphysical considerations; and that his theories were always based upon or controlled by experiment. Nor can we justly apportion the credit due to Mayer without considering the circumstances under which he thought and wrote, or without realising how imperfect (see his correspondence with Bauer and Griesinger) was his knowledge of physics. In the technical skill, the clearness and completeness of Helmholtz's paper "Ueber die Erhaltung der Kraft," we have a complete contrast to Mayer's writings. After an account of the progress which thermodynamics owes to the researches of Clausius and Lord Kelvin, we have the following comparison of the manner in which they presented their investigations to the world.

"In his exposition, Thomson is always quite frank and straightforward in dealing with the difficulties which meet him, the course that he strikes out is always the shortest and simplest, his methods are perfectly clear, and the motives which guide him in his investigations are visible to every one. In Clausius's exposition, there is always a touch of ceremony and reserve. Often one scarcely knows whether Clausius is more concerned to make a statement or to suppress it. The principles of the subject, instead of being deduced from simple experiences, are built up on specially assumed fundamental propositions; these look as though they were more reliable, but do not really offer any greater security than the experiences which might have replaced them. He has, too, a predilection for creating new names and ideas, which are not always necessary. But none of these personal and unessential peculiarities can mar the respect which we feel for Clausius's work."

Further chapters are devoted to the principal propositions in thermodynamics, the absolute scale of temperature, the principle of energy, and the relation between physical and chemical progress.

Up to this point we have nothing but praise for Prof. Mach's treatise: it will do much to revive interest in a subject which has suffered temporary eclipse by the larger developments in recent times of electrical science. The style is clear and forcible, and a due sense of proportion is shown in the arrangement of the subject-matter. We admire his mathematical skill, his critical insight, and the fairness with which he endeavours to apportion praise. The student will find him a trustworthy guide, and the teacher will recognise the frankness of a colleague who knows where the difficulties are and does not slur them over.

To some the remainder of the book will be of equal interest, as it undoubtedly is original, and after the author's own heart. But the reader who has bargained only for a historical and critical exposition of the principles of heat and thermodynamics, may be excused for feeling that he has been betrayed. For in the last twelve chapters Prof. Mach takes the bit between his teeth, and roams at will over the domains of scientific thought, philosophy, psychology, the theory of cognition, language, æsthetics, metaphysics and mysticism. To say that there is a "manifest solution of continuity" between these and what precedes, would be incorrect; but the choice and arrangement of subjects is somewhat kaleidoscopic and bewildering. In the absence of any index, reference is difficult (though here we may be confusing cause and effect). When we want to refer to an ingenious suggestion for inducing sparrows to progress by running instead of hopping, we find it in a footnote to a chapter on "Die Sprache"; while an interesting observation on the suckling and weaning of children finds place in a footnote to a chapter on "Der Begriff." This term (Begriff) is defined in a previous chapter on "Die Vergleichung als wissenschaftliches Princip," in which the author also discusses the question, *Was ist eine theoretische Idee?* Perhaps the most highly variegated chapter is that on "Der Sinn für das Wunderbare."

The proofs of the book have not been carefully read. There are misprints in the German text, and still more in the English quotations and references. The diagrams are numerous and clear, but the half-dozen full-page illustrations are not a great success. Joule is represented by a coarse reproduction of Jeens' engraving. The portrait of Clausius seems to be the best. That of Lord Kelvin is the worst; at any rate, it is as bad as it well could be. *P.T.*

CELL-STRUCTURE AND REPRODUCTION.

The Cell in Development and Inheritance. By Edmund B. Wilson, Ph.D., Professor of Invertebrate Zoology, Columbia University. (Columbia University Biological Series IV.) Pp. xvi. 371. (New York: The Macmillan Company. London: Macmillan and Co., Ltd., 1896.)

ORIGINALLY produced as the substance of a series of lectures of a popular character upon the problems of individual development and inheritance, the book

which Prof. Wilson has given us has taken a form which, while it can hardly longer be described as "popular," will be admitted by the more strictly scientific audience, to which it is now better adapted, to be in the highest degree fascinating. The advances which cellular biology has made, and is making at the present moment, can only be described as "leaps and bounds," and to no part of the study of the cell will this apply with greater force than to that dealing with cell-propagation. A question which seemed to our fathers, and for the matter of that to some of ourselves not so very many years ago, as of the simplest nature and capable of being described in half a dozen lines, can no longer be adequately dealt with except in a volume devoted exclusively to it, and by men who make its study the business of their lives. And although works in other languages upon the subject, such as those of O. Hertwig and Henneguy, are available for the student, it is none the less a matter for congratulation that Prof. Wilson has given us in our own speech a work which is second to none in the clear and comprehensive manner in which the facts of cell-structure and division are set forth, and the masterly way in which the principal theories which have been founded upon these facts are stated and criticised. Not the least striking feature of the book is the lavish way in which it is illustrated—a prime necessity in a work of this kind if it is to be easily read and understood. At the same time it is clear that the illustrations are carefully selected in each case with the object of presenting either a special fact or idea. And although, as might be expected from his position as a zoologist, Prof. Wilson has for the most part relied upon material furnished by the animal kingdom in illustration of his subject, he has not hesitated when occasion has offered to draw upon the important series of observations which have accumulated of late years in vegetable cytology.

The subjects dealt with are, in the first place, the general structure of the cell, the phenomena of cell-division, the special structure of germ-cells (ova and spermatozoa), together with the parts played by the several cell-structures in the process of fertilisation, the formation of germ-cells and reduction of their chromosomes. These subjects occupy some two-thirds of the entire book. Much of the remaining third is occupied by an interesting discussion on the nature and probable function or meaning of the several organised constituents of the cell; including, besides the nucleus and its various parts, the centrosome and the so-called archoplasmic structures, *i.e.* the asters and spindle and attraction-spheres. Their chemical relations and their physiological relations to one another are next passed in review, and, lastly, the most abstruse part of the subject—that, namely, which concerns the relation of cell-division to development and inheritance—is dealt with. The able manner in which Prof. Wilson has succeeded in overcoming the difficulty of presenting the various modern theories of inheritance, which are associated with the names of His, Nägeli, Darwin, Roux, de Vries, Weismann and Hertwig, in a comparatively limited space, and with admirable clearness, can only be appreciated by those who have followed the long and apparently interminable manner in which these theories have, like the Pharaoh's serpents which were popular some years ago gradually extended their voluminous coils from a small and apparently inert mass of material, until a theory is ultimately evolved, which, in Prof. Wilson's language, "demands for the orderly distribution of the elements of the germ-plasm a pre-arrayed system of forces of absolutely inconceivable complexity." "What lies beyond our reach at present, as Driesch has very ably urged, is to explain the orderly rhythm of development—the coordinating power th guides development to its predestined end." "The same difficulty confronts us under any theory we can frame." "The controversy between preformation and epigenesis has now arrived at a stage when it has little meaning apart from the general problem of physical causality. What we know is that a specific kind of living substance, derived from the parent, tends to run through a specific cycle of changes during which it transforms itself into a body like that of which it formed a part." "But, despite all our theories, we no more know how the properties of the idioplasm involve the properties of the adult body than we know how the properties of hydrogen and oxygen involve those of water." "We cannot close our eyes to two facts: first, that we are utterly ignorant of the manner in which the idioplasm of the germ-cell can so respond to the play of physical forces upon it as to call forth an adaptive variation; and second, that the study of the cell has on the whole seemed to widen rather than to narrow the enormous gap that separates even the lowest forms of life from the inorganic world." A statement of fact which we must all have recognised, although few of us ever venture to assert it so boldly as Prof. Wilson has here done.

A characteristic feature of the book is a glossary in which obsolete terms are distinguished from those still in use, and in which also are mentioned the name of the author first using the word, and the date of its employment. This and a sufficiently comprehensive, but not too voluminous, bibliography will greatly add to the general usefulness of this admirable work.

E. A. Schäfer.

PRACTICAL PHYSICS.

An Intermediate Course of Practical Physics. By Arthur Schuster, Ph.D., F.R.S., Langworthy Professor of Physics, &c., Owens College, Manchester, and Charles H. Lees, D.Sc., Senior Assistant Lecturer and Demonstrator in Physics in the Owens College, Manchester. Pp. xv + 248. (London: Macmillan and Co., Ltd. New York: The Macmillan Co., 1896.)

ALL who are engaged in the teaching of physics, and all who are interested in scientific education, will take up this "Intermediate Course" with the certainty of finding much in it that is helpful and suggestive, and they will not be disappointed. It fills a distinct place of its own, between the elementary text-books of practical physics and the more advanced manuals. To some, the fact that it has been primarily written with a view to a particular examination, may be a stumbling-block; but, on close examination, there will be found in it nothing that can be fairly considered as "cram." The authors are fortunate in having had the very best help in drawing it up, namely, the criticism of successive generations of

students who have used the notes from which it is written. In this way it is possible for them to feel certain that, whatever may be the failings of their work, it will at least be intelligible to the average student.

The book opens with a preliminary chapter called "General Instructions," and the practical teacher at once becomes apparent in such paragraphs as that on the importance of *large* errors. No one can have had much experience in teaching practical physics without seeing that the anxiety of beginners to obtain correctness in the second or third place of decimals is accompanied by an extraordinary laxity in noting the tens and hundreds. In fact, it may be said that most of the inaccuracy of beginners in physical measurement is due to this cause. In the chapter on "Arithmetical Calculations," the authors rightly lay stress on contracted methods of multiplication and division. The short chapter on "Graphical Constructions" is less satisfactory than the others, and would probably be improved if some better examples of the method were employed, and if some notice were given to the convention (a most useful one) of making abscissæ represent the independent, and ordinates the dependent, variable.

The body of the book is taken up with experiments on mechanics (including measurement of density and specific gravity), heat, light, sound, and electricity. As necessarily follows from the nature of the case, there is not much that is original in the treatment of these subjects. One admirable feature, however, which runs throughout the course, is the working out of the percentage error in each experiment. In the section on heat, we notice that the calorimeter equivalent is found by pouring warm water into an empty calorimeter; more satisfactory results can generally be obtained by pouring warm water into a calorimeter containing some water at the temperature of the room, and calculating the difference between heat given out by warm water and that taken in by the cold. In this section is also to be noticed an ingenious form of heater for the determination of specific heats by the method of mixtures.

In the optical section the method of tracing rays by means of pins—first used, we believe, in the Cavendish Laboratory—is employed to a considerable extent. There is an experiment on the power of accommodation of the eye, which we have not seen before in any similar work.

The section on "sound" is concerned with the proof of the laws of vibrating strings, and an experiment on the resonance of a column of air. In the last three sections of the book, on "magnetism," "electric currents," and "electric charges," the authors seem to be less successful than in the earlier parts. But it is extremely difficult in the course of fifty pages to give a satisfactory series of experiments on these subjects, especially when, as in this case, a very large number of those pages are taken up with elementary explanations which might have been omitted by reference to any text-book, such as that of Thompson. And the form of water voltameter described is hardly, one would think, the most useful for laboratory purposes, or the most instructive from the point of view of the teacher.

In conclusion we may be permitted to suggest that, from an educational point of view, the book would gain if at the beginning of each experiment a short and clear statement of the object of that experiment were given. One of the most useful results to be obtained from a laboratory course such as this is gained when the student, knowing clearly the question which he is to address to nature, thinks out for himself how he is to proceed in his cross-examination, and compares his method with that of an experienced investigator. D. R.

OUR BOOK SHELF.

Bis an's Ende der Welt! Astronomische Causerien. By Prof. F. J. Studnička. Second enlarged edition. Pp. 212. (Prague: F. Simacek, 1896.)

THE author of this book went to Karlsbad to indulge in the special opportunities afforded by that town in the nature of its waters. During his stay there he made the acquaintance of several other "Kurgäste," by name Bausen, Bugajev, Carpenter, Parelli and Place, and his two friends from Prague, Benda and Naprstek. To pass away the time of their sojourn, these persons formed a small social circle, and, besides taking drives together, they met at stated times and discussed any subject that was uppermost in their minds. Carpenter, however, seemed, from all accounts, to be the dominating one of the party from the discussion point of view, and being of an astronomical turn of mind, the conversations generally were on this subject. His listeners were members of several different professions, so the subject had to be treated in an elementary manner, and, in consequence, the explanations had to be very clear.

The author of this book, who was one of the party, describes here the daily conversations which took place; they are mainly astronomical, although other subjects are occasionally referred to. The astronomical and physical problems dealt with are, for the most part, of a very general character, and will be found interesting reading.

A trip to Prague, after the stay in Karlsbad, gives the author a chance of referring somewhat in detail to the associations, works, and lives of Copernicus, Tycho Brahe, Kepler, Doppler, &c., all of whom were intimately connected with that town.

The book may be said to be quite suitable for the general reader, and the numerous diagrams and illustrations scattered throughout its pages will prove serviceable.

First Stage Inorganic Chemistry. By G. H. Bailey, D.Sc., Ph.D. Edited by William Briggs, M.A. Pp. 210. (London: W. B. Clive, 1897.)

IT is too often forgotten, when criticising text-books written to follow the lines laid down in syllabuses, that the books are not so much to be blamed as the syllabuses. For convenience, it is considered necessary to state the subjects of which a student who presents himself for examination will be expected to know something. The text-book is then produced, in order that the student shall be able to acquire the knowledge in as easy a way as possible. If the syllabus is badly arranged, the text-book designed to meet it will be a bad one; but if the subjects in it are placed in an educational sequence, the text-book will partake of that good quality. Probably no one is better able to judge whether a syllabus hangs together properly or not, than a competent scientific writer who tries to build a book upon it.

The book before us has been arranged to meet the requirements of the Department of Science and Art for the Elementary Stage of Inorganic Chemistry. In eighteen short chapters the author deals with the general principles of chemistry, the nature of chemical reaction, the chief non-metals and their most important compounds, physical properties of gases, chemical nomen-

clature, and chemical calculations. At the end of each chapter is a summary, and a number of questions to test the student's progress. Considerable attention is given to experiment, and the aims and purposes of the study of chemical science are brought into prominence. In fact, though the volume is one of a class of much-maligned text-books, and though it is intended for students working for examination, it is, nevertheless, a book which presents the rudiments of chemistry in a form which will make students appreciate the value of experiment as an instrument of scientific research.

Encyclopédie scientifique des Aide-Mémoire. Edited by M. Léauté. (Paris: Gauthier Villars et Fils. Masson et Cie.)

THREE new volumes have recently appeared in this very serviceable series of technical handbooks. They are as follows:—

"Les Piles Électriques." By Ch. Fabry. This volume deals with the theory of the various electric cells, the measurement of the electromotive force and resistance of such cells, the construction of ordinary electric cells, and standard cells.

"Les Machines Thermiques." By Prof. Aimé Witz. Heat engines generally, steam engines, hot-air engines, and gas engines form the main subject of this volume. The object of the book is to institute a comparison between various heat machines, so as to bring into prominence the special characters of their respective cycles. Chapters are devoted to atmospheric machines, compressed-air machines, and freezing machines. Elementary students of thermo-dynamics will find the book interesting.

"Les Gaz de l'Atmosphère," by M. H. Henriet, is an excellent little volume on the chemistry of the atmosphere. The author is chemist at the Montsouris Observatory, and the methods of analysis described by him, as well as the results of investigations into the composition of the air at different places and at different times, makes his little book very valuable to meteorologists as well as chemists.

The Dahlia: its History and Cultivation. By various Writers. Pp. 81. (London: Macmillan and Co., 1897.)

THE history of the dahlia is told in this handbook by Mr. Richard Dean; the botany is described by Mr. John Ballantyne; the propagation and exhibition of the dahlia are dealt with by Mr. Stephen Jones; and the cultivation by Mr. Robert Fife; while Mr. William Cuthbertson, the editor of "Dobbie's Horticultural Handbooks," to which series the present volume belongs, contributes an introduction. The book is interesting to the botanist as well as the florist, and it should be possessed by every one who finds delight in cultivating dahlias. Of especial value to floriculturists is a full and classified catalogue of varieties of the dahlia, and selections for various purposes. The varieties are arranged alphabetically, and the characteristics of each are described.

La Cause Première d'après les Données Expérimentales. By Émile Ferrière. Pp. 462. (Paris: Félix Alcan, 1897.)

THIS volume is the third and last of a trilogy having for their object the demonstration of the unity of substance by means of established facts, *à priori* argument being excluded. In the first volume the unity of the laws of matter and energy throughout the universe was expounded; the second volume dealt with the physical, physiological, embryological, and pathological facts concerning life and mind; the present volume aims at explaining the relations between various forms of organic life, the order of appearance of animals and plants upon the earth, and evolution problems generally. Leaving the metaphysical side of the book out of consideration, the book contains a certain amount of readable information and criticism.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Acquired Immunity from Insect Stings.

MAY I beg to add a few lines to the very interesting correspondence and discussion regarding the immunity of man from insect-stings and snake-bites after successive inoculations. The letter of Dr. Dawson Williams, in NATURE of March 4, calls attention to a certain degree of immunity which obtains among the Norwegians from the stings of the myg, a kind of gnat (probably our midge, Anglo-Saxon mygge). His statements in regard to the degree of immunity varying in different individuals, is quite in accordance with our experience with the mosquito. His pathological description of the effects of the sting of the Norwegian myg would apply most accurately to the sting of the mosquito. We also become more or less immuned from the mosquito poison after much suffering in childhood. The swelling resulting from the mosquito sting will often close the eyes of an infant. In middle age the sting is hardly noticeable. English and Irish people, upon first coming to this country, suffer beyond measure, and often come under the care of a surgeon. It is a curious yet painful sight to see a brawny Englishman presenting the appearance of our young infants under the infliction of these pests. I have two Irish servants, who have been in this country two and seven years respectively. They both tell me that the mosquito bite, as it is called, no longer troubles them, though they were eloquent in the descriptions of their acute sufferings at the outset. More than a quarter of a century ago Dr. J. C. White, a distinguished dermatologist, of Boston, in a communication to the Boston *Medical and Surgical Journal*, November 9, 1871, discusses the subject fully in a paper entitled, "On the protection acquired by the human skin and other tissues against the action of certain poisons after repeated inoculation." He not only shows the immunity arising from the repeated stings of mosquitos, but notices a like immunity arising from the domestic pests, Pediculus, Cimex and Pulex. An American recalls his first experiences with the flea in Europe with the same horror that an Englishman remembers the welcome he received from the mosquito in America.

More than a century ago attention was called to the immunity enjoyed by natives to the sting of mosquitos. In the efforts of Great Britain to suppress the revolt in the American colonies, European troops were hired to augment their armies. Among these were the Anspach-Bayreuth troops, and this contingent was accompanied by an intelligent surgeon, Dr. Johann David Schoepll. His letters to Prof. Delius, of Erlangen, on the "Climate and Diseases of America," were published in pamphlet form in 1781. Dr. James R. Chadwick, of Boston, translated the pamphlet as being one of medico-historical interest. The following paragraph from these letters is of interest. The author says: "One fact is worthy of mention in this connection, which perhaps testifies as forcibly as anything can to the need of acclimatisation, and is moreover universally admitted to be true. In a new-comer, almost every bite of the mosquito produces a boil during the first year after his arrival, but fails to have this effect in the subsequent years."

EDWARD S. MORSE.

Salem, Massachusetts, March 22.

To the query of Mr. Dawson Williams (NATURE, March 4, p. 415), as to whether the mosquito injects a toxin, an affirmative answer may be given. The mosquito has, instead of the two long simple salivary glands of other diptera, a complex system, three glands on each side of its thorax, two of each set unlike the third. All the six ductules from these glands unite so as to carry the secretion to the common salivary duct, and by it to the hypopharyx. The structure of the hypopharyx is the same as that of the sting of a bee, a tubular-pointed organ with a subterminal orifice. The only exit for the discharge of the complex glandular apparatus is into the wound made by the lancet-formed mouth-organs.

I have all this mechanism dissected out and preserved for

microscopic examination; and it was figured in the *American Naturalist* of September 1888. G. MACLOSKIE.
Princeton University, U.S.A., March 24.

The Affinities of "Hesperornis."

IN the autumn of 1870, I discovered, in the Cretaceous of Western Kansas, the remains of a very large swimming-bird, which in many respects is the most interesting member of the class hitherto found, living or extinct. During the following year, other specimens were obtained in the same region, and one of them—a nearly perfect skeleton—I named *Hesperornis regalis*.[1] In subsequent careful researches, extending over several years, I secured various other specimens in fine preservation, from the same horizon and the same general region, and thus was enabled to make a systematic investigation of the structure and affinities of the remarkable group of birds of which *Hesperornis* is the type. The results of this and other researches were brought together in 1880, in an illustrated monograph.[2]

In the concluding chapter on *Hesperornis*, I discussed the affinities of this genus, based upon a careful study of all the known remains. Especial attention was devoted to the skull and scapular arch, which showed struthious features, and these were duly weighed against the more apparent characters of the hind limbs, that strongly resembled those of modern diving birds, thus suggesting a near relationship to this group, of which *Colymbus* is a type. In summing up the case, I decided in favour of the ostrich features, and recorded this opinion as follows:—

"The struthious characters, seen in *Hesperornis*, should probably be regarded as evidence of real affinity; and in this case *Hesperornis* would be essentially a carnivorous, swimming ostrich" ("Odontornithes," p. 114).

This conclusion, a result of nearly ten years' exploration and study, based upon a large number of very perfect specimens, and a comparison with many recent and extinct birds, did not meet with general acceptance. Various authors, who had not seen the original specimens, or made a special study of any allied forms, seem to have accepted without hesitation the strikingly adaptive characters of the posterior limbs as the key to real affinities, and likewise put this opinion on record. The compilers of such knowledge followed suit, and before long the Ratite affinities of *Hesperornis* were seldom alluded to in scientific literature.

Several times I was much tempted to set the matter right, as far as possible, by reminding the critics that they had overlooked important points in the argument, and that new evidence brought to light, although not conclusive, tended to support my original conclusion that *Hesperornis* was essentially a swimming ostrich, while its resemblance to modern diving birds was based upon adaptive characters. On reflection, however, I concluded that such a statement would doubtless lead to useless discussion, especially on the part of those who had no new facts to offer, and, having myself more important work on hand, I remained silent, leaving to future discoveries the final decision of the question at issue.

It is an interesting fact that this decision is now on record. A quarter of a century after the discovery of *Hesperornis*, and a decade and a half after its biography was written in the "Odontornithes," its true affinities, as recorded in that volume, are now confirmed beyond dispute. In the same region where the type specimen was discovered, a remarkably perfect *Hesperornis*, with feathers in place, has been found, and these feathers are the typical plumage of an ostrich.[3]

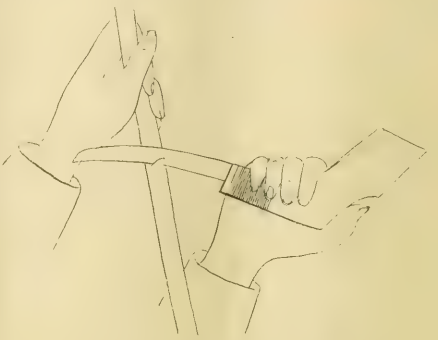
O. C. MARSH.
Yale University, New Haven, Conn., March 16.

The Antiquity of Certain Curved Knives.

IN the United States National Museum are a number of knives which go by the general name of "curved knives." The figure here shown is from Anderson River, Mackenzie River district, and is an exaggerated form of the implement mentioned. The essential features are a blade curving upward, so that in cutting it is moved towards the body, and not away from it as in ordinary whittling; this blade is fastened to a handle which is grasped by the four fingers, the thumb resting in a bevel at the butt end. The Canadian voyager uses this knife in making snow-shoes, canoes, and in wood-working generally.

Somewhat modified specimens come from Alaska, wherever drift wood is utilised by the natives in making household and other utensils, and from the Pacific Coast of North America. The same form is found in abundance along the eastern coast of Asia, as far south as further India. The "farrier's knife" of England is formed and used on the same principle.

I am very curious to know the antiquity of this form of knife, and to find out the earliest date when it was introduced into America. I am not familiar with any examples from southern Europe, although, anciently, this pattern may have entered into the common mechanical life of people there.



In connection with this knife, it is pleasant to know that, while a great multitude of aboriginal arts have been degraded by contact with the white race, wherever this knife has gone the savage art has been greatly improved and perfected.

The primitive and old-fashioned snow-shoe, with a rough stick bent into pear-shape for the frame, the filling being of the coarest raw hide, must be compared with the delicately made frame and fine and uniform babiche of the modern snow-shoe, to give force to this declaration.

I am making a collection of knives of this class, together with information concerning their distribution, forms and uses.
U.S. National Museum. OTIS T. MASON.

The Function of Disease in the Struggle for Existence.

PROF. A. DE QUATREFAGES ("The Human Species," p. 430), discussing the decline of the Polynesian Races, remarks:—"Two naval surgeons, MM. Bourgarel and Brulfert, have alone been able to throw some light upon this melancholy problem. The former found that tubercles were *invariably* present in the lungs of bodies submitted to post-mortem examination. The latter tells us that all Polynesians suffer from an obstinate cough, and that, in eight cases out of ten, tuberculosis follows these bronchial catarrhs. Now, phthisis does not appear in the list of diseases drawn up by the old voyagers."

As is well known, the climate of New Mexico is extremely unfavourable to the development of pulmonary tubercle, and consequently this disease seems to have been formerly absent among the native Mexicans. But I have been informed that Mexican girls serving in houses where there are consumptive invalids sometimes contract phthisis, which, in this climate, must indicate a high degree of constitutional susceptibility. *Per contra*, the Mexicans appear to survive small-pox more easily than Europeans, if not also more immune from its attacks, and this, doubtless, may be explained by the fact that they take no precautions to avoid it, and consequently allow selection by disease full play, as was suggested to me by Dr. Lyon, of Las Cruces.

[2] "Odontornithes: a Monograph on the Extinct Toothed Birds of North America." 4to, 34 plates, Washington, 1880.
[3] Williston, *Kansas University Quarterly*, vol. v. p. 53, July 1896.

Texas fever in cattle, due to a protozoon parasite of the blood, is endemic, and practically harmless in the south; but when southern cattle are driven northward, and mixed with northern cattle, the latter contract the disease in a form which is rapidly fatal.

The above facts are selected out of many of a similar kind that are on record. It will be generally admitted that a race or species which has long been subjected to a zymotic disease acquires by selection a relatively high degree, if not of immunity, of endurance of the disease.

It does not seem to have been sufficiently appreciated by naturalists that it may be beneficial to a species, in the struggle for existence, to *retain the susceptibility to attack while developing the power of endurance*, instead of acquiring a total immunity from attack.

When a species or race, thus subject to a mild form of a zymotic disease, meets the territory of a closely-allied species or race, it is evident from such cases as are cited above, that the disease, communicated to the newly-met race, may prove a most powerful agent for destruction, with the result of leaving a new territory open to the invaders.

It has only lately been realised how susceptible insects are to various obscure diseases due to bacteria and fungi. In fact, in my studies of the Coccidæ, I have come across numbers of parasitic fungi, which appear to be wholly undescribed and unknown. Therefore, when one insect supplants another in the mysterious way it sometimes does, it is easy to imagine the factor of communicable disease playing an important part.

The purpose of this note is simply to draw attention to the matter, and to request those of your readers who may witness the supplanting of a native animal or insect by a foreign or invading one, to particularly note whether the former is attacked by any disease. T. D. A. Cockerell.

Mesilla, New Mexico, U.S.A., March 9.

The Caucasus.

It might be out of place to trouble your readers with any lengthy discussion of the many difficulties and snares that beset the path of the transcriber of Caucasian place-names, and of the discrepancies to which they may easily give rise. Nor shall I ask you for space to defend, in any detail against your reviewer's strictures, my own system—or want of system—in dealing with Caucasian nomenclature. In so far as I may have deviated from the principles laid down by the Committee of the Royal Geographical Society, of which I was a member, and adopted by the British Admiralty, the Government of the United States, and other bodies, I am very ready to submit myself to expert criticism or correction.

In these notes, however, my object is not so much personal as general. It is to prevent the confusion of knowledge, and to a certain extent of tongues, which, I fear, must ensue should men of science in search of information about the Caucasus attempt to follow, without some further advice, "J. W. G.'s" summary suggestions.

In the first place, I have to point out that your critic has failed to take into account a circumstance which is, in my opinion, of great importance, and to which, in my preface, I was at pains to call particular attention. The Caucasus, as we all know, is an annexed or conquered country. Consequently its place-names are not Russian, but, in the district with which I deal, for the most part Old Turkish or Georgian. Now scientific cartographers in this country are not, I believe, prepared, wherever and whenever Russia may incorporate an Asiatic district, to substitute for the English forms of the native place-names transliterations from the forms they assume in Russian maps. Such a course has obvious disadvantages. It must obscure the meaning of many names, and give identical names different forms, according as they occur within or outside a political frontier. The question is a recurrent and a difficult one, not to be set aside lightly by an *obiter dictum*, or by an appeal to French usage. Under no circumstances, I must add, are British geographers likely to respond to your writer's implied suggestion by assimilating their system to that in use in France.

"J. W. G." and I agree, I am glad to find, in desiring to induce men of science in quest of accurate information as to the Caucasus, to seek it out from first-hand authorities. He recommends certain articles, printed in Russian, and published in Moscow and Tiflis periodicals by MM. Dinnik and Jukoff. I have good reason to believe that a knowledge of Russian is still far from universal, even among men of science. I shall therefore venture to suggest that our countrymen may gain some further assistance from the hundreds of pages devoted to the Caucasus, during the last ten years, in the *Journals* of the Alpine Club and of the Royal Geographical Society. And I would add a few words of caution to beginners. M. Dinnik's paper was written some years ago, when the New Survey was still far from complete, and his own travels did not suffice to fill in the gaps. On some matters, consequently, he may mislead—and has misled—his copyists. M. Mikhailovsky's tables of Caucasian Peaks, Passes, and Glaciers, issued in the Moscow *Zemlevyedyenie*, should also be consulted. They are more up to date, and detailed, though he, too, fails in the personal knowledge of the localities essential to graphic and accurate description. Moreover, his spelling of place-names frequently diverges from that of the preliminary sheets of the New Survey, privately communicated to me by the Surveyors, which were my authority.

It is with some surprise that I observe your critic's statement that he has failed to find in my pages any reference to the writings of either M. Dinnik or my friend M. Jukoff. The former, I must confess, has slipped out of my index. But he is referred to in his proper place in the first chapter, and elsewhere. M. Jukoff is in my index, preface, first and many other chapters. I have mentioned both frequently in the Alpine and Geographical *Journals*, and I published a translation of a paper of M. Jukoff's in the latter periodical. As to the map of M. Fournier's, which "J. W. G." cites, it is a geological map appended to a geological diploma essay printed at Marseilles last autumn. It can hardly, I think, be cited as a *geographical* authority.

Douglas W. Freshfield.

The Alpine Club, March 20.

We did not intend our remarks on nomenclature to be strictural, and we certainly offered no suggestions, summary or otherwise. We only pointed out some of the inconsistencies inevitable when place-names are not transliterated upon a definite system. The fact that the Caucasian place-names are derived from various languages had not been overlooked; but the rules laid down by the R. G. S. Committee, to which Mr. Freshfield refers, admit the principle in such cases of accepting the spelling of a standard national gazetteer or of official survey maps. Such a method may be philogically defective, but it is geographically convenient. Would Mr. Freshfield recommend a foreign geographer, writing about England, to abandon the recognised names in favour of the forms which may be used locally? To ignore the official spelling in many parts of the Russian Asiatic dominions would be to render the revision of place-names, to use Mr. Freshfield's term, a "recurrent" difficulty, for the people are nomadic, and names come and go like fashions. There is probably no place for which a stronger case could be made out in favour of adopting the spelling of the official maps. We did not imply that the French method should be adopted in England; what we said was that, owing to the variations adopted by Mr. Freshfield, sometimes avowedly for the sake of appearances, it was difficult to find his names in Fournier's map. We did not quote Fournier as a geographical authority. In regard to the two Russian authors to whom we referred, we remarked the absence of reference to their technical papers, instead of to those of general Western compilers, for information respecting the Caucasian glaciers. J. W. G.

The Laboratory Use of Acetylene Gas.

It is evident from Mr. Munby's letter, in your issue for March 25, that he is unaware that atmospheric burners adjusted for acetylene gas are, and have been for some time, articles of ordinary commerce. Up to the present time no satisfactory method has been found by which large and powerful Bunsen flames can be obtained free from smoking, as the mixture of acetylene gas with a small proportion of air is very explosive, and the Bunsen tubes used must not exceed 3-16 inch diameter. Any ordinary Bunsen adjusted for 20-candle coal gas, if not exceeding the bore stated, will be found fairly satisfactory with acetylene, the gas pressure being not less than 5 inches of water; but the best results are obtained from burners rather different in proportions from the ordinary laboratory Bunsen.

Warrington. Thos. Fletcher.

NEW WORKS ON THE CLASSIFICATION OF LEPIDOPTERA.[1]

THE satisfactory classification of *Lepidoptera* has always been regarded as one of the most difficult problems in entomology, and many authors (chiefly English and American) have recently been working at the subject, and trying to throw fresh light upon it from the supposed lines of descent of the insects, and from a critical and comparative study of their earlier stages. It is, however, somewhat to be regretted that most of the systems follow very different lines, and therefore arrive at very divergent results. This is only the consequence of the now generally recognised impossibility of arranging natural objects in a linear series which shall represent their real affinities; and in due time we may hope that some compromise may be arrived at, which will reconcile the opposing systems so far as to lead to a fairly satisfactory and uniform result.

The first book on our list professes to give a more complete and trustworthy account of our few British butterflies (a theme which we should have thought was worn almost threadbare by this time) than has heretofore appeared. However, Mr. Tutt may fairly claim to have produced a book in which the early stages of the insects are dealt with in greater detail than in almost any previous English work not devoted exclusively to larvæ, except Newman's; and he has also fully enumerated the varieties of our British species in all parts of their range, though he rarely alludes to allied continental species, even if reputed British. His account of the systematic extermination of such species as *Melitæa athalia* and *Apatura iris* (both common, quite close to London, not so very many years ago) will be read with interest and pain by every right-thinking entomologist. In some cases, his information is hardly up to date, as, for instance, with respect to the history of *Chrysophanus dispar*. Mr. Tutt's preliminary chapters are devoted to the early stages of butterflies, and to instructions on collecting, rearing, and preserving. But here, too, our author seems to write exclusively for *British* entomologists, for the continental high setting (now coming into use in England among collectors of exotic Lepidoptera) is not even mentioned.

Mr. Tutt's classification does not depart much from the Batesian system, except that he follows an ascending instead of the usual descending system, commencing with the *Hesperidæ*, and ending with the *Satyridæ*. He has adopted the American system of "superfamilies," ending in "-ides," of which he admits two, the *Hesperides* and the *Papilionides*, which he divides into families ending in "-idæ," subfamilies, ending in "-inæ," and "tribes" ending in "idi."

The second work on our list, by one of the leading American entomologists, though dealing chiefly with but a single family of North American moths, the *Notodontidæ*, includes an elaborate introduction, in which the supposed descent, the structure and affinities of the various families of *Lepidoptera* are discussed, with special reference to their early stages. The plan of Dr. Packard's researches may be gathered from the following remarks:

"Until within a few years the majority of descriptions of caterpillars have been prepared simply for the purpose of identification, or for taxonomical uses, and without reference to the philosophic or general zoological significance of these changes. The transformations of some of the European Sphingidæ have been very carefully worked out by Weismann, and also by Poulton; but it is believed that the life-histories of the lower, more generalised families usually referred to the Bombyces, especially of the Notodontidæ, Ceratocampidæ, Saturniidæ, Hemileucidæ, Cochliopodidæ, and Lasiocampidæ will bring out still more striking and valuable results, inasmuch as they, or forms near them now extinct, are believed to be closely similar to the stem forms from which many of the higher Lepidoptera have probably been evolved.

"The aim, therefore, in such studies should be:

"(1) To treat the larvæ as though they were adult, independent animals, and to work out their specific and generic as well as family characters.

"(2) To trace the origin of mimetic and protective characters, and to ascertain the time of larval life when they are assumed, involving

"(3) The history of the development of the more specialised setæ (hairs), spines, tubercles, lines, spots, and other markings.

"(4) To obtain facts regarding the ontogeny of our native species and genera which, when added to what we know of the life-histories of European, Asiatic and South American Bombyces, may lead to at least a partial comprehension of the phylogeny of the higher Lepidoptera, viz. those above the so-called Micro-Lepidoptera."

It is really the immense amount of detail which renders it so difficult to arrive at a correct classification of animals. In the case of *Lepidoptera*, it is comparatively easy to compare egg with egg, pupa with pupa, and imago with imago; but we should then only arrive at a very superficial knowledge of the species; for the caterpillars moult several times, and their structure also differs very much in these various stages, and we can only arrive at correct conclusions by comparing each of the corresponding stages; and it is frequently the earliest of these which throw most light on the affinities of the species. Thus, to take our well-known British swallow-tail butterfly as an example, the very young larva is set with fleshy tubercles, like the full-grown larvæ of *Ornithoptera*, and other exotic forms belonging to the same family.

In the special part of his work Dr. Packard has described the North American *Notodontidæ* in all their stages, and has not only given illustrations (mostly plain) of the moths themselves, but has added a series of beautifully executed coloured drawings of the larvæ of numerous species in their various stages, special attention being given to the earlier ones. Plates of neuration, and maps showing the geographical distribution of many species, are also added.

To return to the Introduction, we find sections on the mode of evolution of the bristles, spines, and tubercles of Notodontian and other caterpillars; on the incongruence between larval and adult characters; on inheritance of characters acquired by larvæ; geographical distribution; phylogeny; classification; and nomenclature of wing-veins, &c.

The enormous mass of matter (largely original) which Dr. Packard has brought together, makes it difficult to discuss his work in detail. But we may notice one or two points of special interest. His researches have led him to the conclusion that the Lepidoptera originated from some probably extinct form intermediate between the Panorpidæ and the Trichoptera; and he suggests that the earliest type of lepidopterous larva was allied to some Tineoid feeding on low herbage on land, not being a miner or sack-bearer, as these are evidently secondary adaptive forms. Some of the larvæ figured exhibit very remarkable appendages in their early stages, which disappear after the first or second moult. Among the most curious are the huge branching "antlers" on the prothoracic segments of the larvæ of different species of the

[1] "British Butterflies, being a popular handbook for young students and collectors." By J. W. Tutt, F.E.S., Editor of *The Entomologist's Record and Journal of Variation*. 8vo. Pp. 476; pls. 10, and woodcuts. (London: George Gill and Sons, 1896.)

"Monograph of the Bombycine Moths of America North of Mexico, including their Transformations and Origins of the Larval Markings and Armature." Part 1. Family 1. Notodontidæ. By Alpheus S. Packard. (National Academy of Sciences, vol. vii.) 4to. Pp. 291; pls. xlix.; maps 2 (1895).

"Die Saturniiden (Nachtpfauenaugen)." Von A. Radcliffe Grote, A.M. (Mittheilungen aus dem Roemer-Museum, Hildesheim. Nr. 6, Juni 1896.) Pp. 30; pls. iii.

genus *Heterocampa*, which remind us of the strange appendages exhibited by the perfect insects of some *Homoptera*. As regards classification, Dr. Packard refers chiefly to the writings of Dr. Chapman, Prof. Comstock, and Mr. Walter; and after some criticism, he proposes the following scheme:—

Sub-order I. Lepidoptera Laciniata, or Proto-Lepidoptera (Eriocephala).

Sub-order II. Lepidoptera Haustellata.

I. Palæo-Lepidoptera (Micropteryx).

II. Neolepidoptera.

Dr. Packard's phylogenetic tree of the last section, which comprises all the *Lepidoptera* except *Micropteryx* and *Eriocephala*, is suggestive.

He recognises six main stems, one of which, the *Hepialidæ*, has no offshoot; four of the others are short, culminating in the *Megalopygidæ*, *Cossidæ*, *Sesiidæ*, and *Pyralidinæ* respectively, while the sixth leads up from the *Prodoxidæ* past the *Psychidæ* and *Zygænidæ*, through the *Tineidæ*, to the *Lithosiidæ*, whence arise other branches, culminating in the *Nymphalidæ*, *Sphingidæ*, *Geometridæ*, and *Arctiidæ*.

We have said enough to indicate the immense interest and importance of this work, not only to all lepidopterists, but to all who are interested in the philosophic study of evolution. When will Governments or adequately supported Societies or Universities render it possible for similar works to Dr. Packard's to be executed and published in Europe?

Telea Polyphemus (Cramer) at rest.

Mr. A. R. Grote, who has probably described more North American Lepidoptera than any other author, has lately taken up his abode in Germany, but has not therefore abandoned his interest in entomology. In the course of last year he published a sketch of the classification of *Lepidoptera* (partly following Comstock's system), in which he recognised a "super-family Bombycides," divided into four families—Bombycidæ, Endromidæ, Agliidæ, and Saturniidæ. In the present paper he modifies his views on the phylogeny of these families, and concludes, from his own and Dr. Dyar's observations on the earlier stages of the larvæ of *Bombyx* and *Endromis*, that they are allied to the *Lachnæidæ* (*Lasiocampidæ*), which is the first family of his "super-family" Agrotides (which includes the bulk of the Bombyces and Noctuæ), which must now take the name of Bombycides, leaving the "super-family" Saturniides to include only the two families Saturniidæ (sub-families *Attacinæ*, *Saturniinæ*, and *Hemileucinæ*); and Agliidæ (sub-families *Agliinæ*, *Automerinæ*, and *Citheroniinæ*. We are puzzled by the remark that the discovery of the larva of the Australian genus *Chelepteryx* may throw light on the position of *Endromis*. Is he unaware that the full-grown larva of *Chelepteryx*, as figured by Scott, is covered with bristle-bearing warts, and is thus totally different from that of *Endromis*?

This paper also includes an analytical table of the genera of *Saturniidæ*; and several genera, founded on known species, are indicated as new. Special attention is paid to larvæ, neuration, and antennæ, in working out the phylogeny of the groups (of which a tentative table is given), and the neuration and antennæ are illustrated with woodcuts. A special feature of interest is formed by the three photographic plates—one representing cocoons, and the others, taken from the living insects, representing the positions of several of the moths in repose. One of these is reproduced on this page. The paper concludes with a revised synonymic list of the North American Saturniides.

THE ZÜRICH FEDERAL POLYTECHNIC SCHOOL.

A RECENT number of the *Revue Générale des Sciences* contains a very interesting account of the Federal Polytechnic School at Zürich. Switzerland possesses one other such institution, namely, that at Lausanne.

The Federal Polytechnic School at Zürich is the only institution in that country, connected with higher education, which depends on the Confederation directly. As a natural result the school is much richer, and has been able to develop more rapidly. The students are all day scholars, and are divided into two classes: the *reguliers*, that is, those who go through a fixed course, and the *auditeurs*, those who work chiefly in the advanced division. The school opened in 1855 with 228 students. This number has increased every year, and in 1895 reached the total of 757. The courses of instruction are arranged under the seven following heads: (1) architecture, (2) civil engineering, (3) industrial mechanics, (4) industrial chemistry, (5) agriculture, (6) pedagogy, and (7) an optional course, in harmony with the six other divisions, which includes history, literature, modern languages, political economy, statistics, philosophy, fine art, and military tactics.

While endeavouring to preserve the character of a higher technical school, the theoretical instruction is also carried on as far as possible. The school has from the Confederation an annual subsidy of eight hundred thousand to nine hundred thousand francs, besides numerous other subsidies and revenues. With this income of over one million francs, not only are general expenses covered, but a number of additions can annually be bought. No money has, moreover, been spared on the erection of the laboratories, which are very numerous and spacious.

Fig. 1 represents the chemical school. It contains photographic, microphotographic, and pharmaceutical laboratories. The chemical analytical laboratory contains 166 single places, or 83 double; the double places, consisting of two tables back to back, are given to the more advanced students. Adjoining this laboratory are two balance-rooms, a dark-room, a room for electrolysis, one for analyses of gases, two for work of more advanced students, and another for physical chemistry. The laboratories for industrial and analytical chemistry are also divided into similar rooms.

The astronomical observatory is shown in Fig. 2, the principal feature of the illustration being the

Fig. 1.

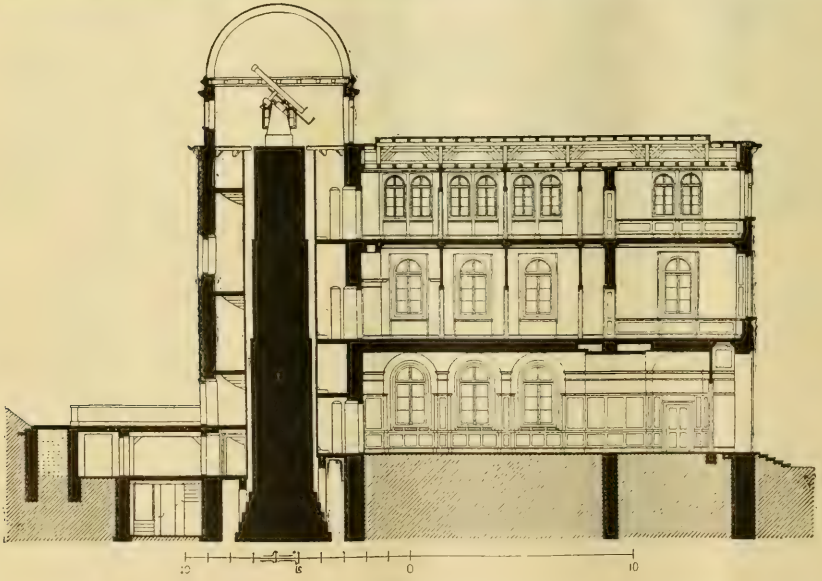

Fig. 2.

immense concrete pillar on which the equatorial rests. In addition to the laboratories already mentioned, there is an institute for physics, for photography, a workshop for modelling in clay and plaster, in connection with the course on architecture; a workshop for working on metal and wood, in connection with the mechanical

division; and, also, laboratories for pharmaceutical purposes and agricultural chemistry.

From this sketch it will be gathered that the courses of instruction are not only well provided for as regards laboratory equipment, but are thoroughly suited to the requirements of the students in every subject included in the syllabus.

SCIAGRAPHS OF BRITISH BATRACHIANS AND REPTILES.[1]

ON May 5 last, Mr. G. A. Boulenger, F.R.S., reading a paper before the Zoological Society of London, on "Some little-known Batrachians from the Caucasus,"

Fig. 1.

announced (*cf. P.Z.S.*, 1896, p. 552) the first outcome of the application of the Röntgen rays to herpetological investigation, having by their aid settled the systematic position of a unique batrachian without injury to the specimen. The event aroused in the minds of Messrs. Green and Gardiner a determination to repeat the experiment on a larger scale, with the result now before us—viz. a series of sciagraphs of all the British Batrachians and Reptiles, including the rare Smooth Snake (*Coronella austriaca*).

Two or three of the plates are indefinite, perhaps as the result of light printing, but the majority, for clearness and sharpness of definition, mark a very considerable advance upon anything of the kind yet published, and enable us the better to judge of the possibilities of the method as an aid to zoological and anatomical study. The plate of the Crested Newt (Fig. 1), which we reproduce, is especially noteworthy in this respect, and for the clearness with which the ossific nuclei of the carpus and tarsus are recorded. In the case of bones which, like these, are well isolated, and of those which are rod-like and dense, the method leaves little to be desired for purposes of general study and orientation of parts. Where thin flat bones exist, however, detail is not recorded; and as concerning the cranium, to which this remark especially applies, the appearances

Fig. 2.

presented by some of the plates suggest delimitation of brain structure rather than anything that is osteological. Be this as it may, it is important to observe that marked indications of the soft parts occur in some of the prints—most conspicuously in the case of the large intestine, especially when fully laden with egesta largely composed of the elytra of beetles ingested as food. The area of overlap of the segments of the limbs and of not a few of the individual limb muscles is also rendered evident.

Detail is greatest in the figure of the Natterjack Toad, which we also reproduce (Fig. 2). Its lungs (like those of the frog of which a sciagraph by Messrs. Reid and Kuenen

[1] "Sciagraphs of British Batrachians and Reptiles." Thirteen plates mounted, with portfolio. By J. Green and J. H. Gardiner. (Wallington, Surrey, 1897.) With an introduction by G. A. Boulenger, F.R.S.

appeared in NATURE, vol. liii. p. 419) were unequally inflated. Not only can the texture of both of them be satisfactorily made out, but on the right side there is a uniformly tinted hemi-cardiac-shadow, indicative of the greatly thickened right lobe of the liver. Indications of the base of the stomach are also to be made out, and on both sides of the body there are feeble shadows at places coincident with the oviducts.

Messrs. Green and Gardiner have also favoured us with an advanced print of a sciagraph of a *Pelodytes*, which is in some respects sharper than those which they have placed on the market. They are continuing the work, and have recently exhibited before the Linnean and Malacological Societies sciagraphs of molluscs no less successful than those here under review—for they have obtained from the entire *Nautilus* a pictorial record of the muscle scars and lines of origin of the septa (a reprint of which is shortly to appear in the Proceedings of the Malacological Society), and from an entire Chiton of the plate-margins, which lie beneath the body-wall and are of primary taxonomic importance.

Mr. Green is one of our most accomplished zoological lithographers. Recent plates of his, which have appeared in the British Museum Catalogue of Snakes, and in the Proceedings of the Zoological and Malacological Societies, lead us to hope that in some departments of the work he may outrival his foreign contemporaries; and with the Röntgen rays he and his colleague have been no less successful. Their portfolio is elegantly got-up; and its value is materially enhanced by an accompanying introduction, dealing with geographical distribution and structure, from the pen of the distinguished herpetologist whose work incited them to action. We shall watch with intense interest the development of their enterprise, which has already produced results of the greatest service to the student of animal life.

NOTES

THE names of those who attended Prof. Sylvester's funeral, copied from the *Times*, were by inadvertence inserted at the end of Major MacMahon's article, instead of beneath his signature.

M. RADAU has been elected a member of the Section of Astronomy of the Paris Academy of Sciences, in succession to the late M. Tisserand.

SIR JOHN EVANS, K.C.B., Treasurer of the Royal Society, has been elected a Corresponding Member of the Academy of Sciences of Bologna, in succession to the late Right Hon. T. H. Huxley.

PROF. ALBERT VON KÖLLIKER, the eminent professor of anatomy in the University of Würzburg, has had the title of "Excellency" conferred upon him.

DR. LAUDER BRUNTON, F.R.S., will give one of the general addresses at the forthcoming International Medical Congress in Moscow.

PROF. E. RAY LANKESTER, F.R.S., will preside over the meeting of the Museums Association, to be held at Oxford on July 7–9 of this year.

THE ninth meeting of the International Congress of Hygiene and Demography, which was to have been held at Madrid in October of the present year, has been postponed till April 1898.

DR. H. E. ARMSTRONG, F.R.S., has been elected a member of the Athenæum Club, under the rule which empowers the annual election by the Committee of nine persons "of distinguished eminence in science, literature, the arts, or for public services."

A FINE bronze statue of the late Sir Richard Owen has just been placed in the Natural History Museum, South Kensington, facing the statue of Darwin. The funds for the statue were raised by public subscription.

WE regret to have to record the death of Dr. G. A. Kenngott, for many years professor of mineralogy in the University of Zürich, and director of the mineralogical museum there.

A REUTER'S telegram from Ottawa says that the Canadian Government intends to begin immediately the works for enlarging and deepening the canal system in the Dominion, securing a uniform depth of 14 feet from Lake Superior to Montreal, at an estimated cost of 10,000,000 dollars.

ACCORDING to a telegram which the *Lancet* has received from Bombay, the Yersin serum treatment of plague has practically failed. So far the mortality has been 50 per cent. in the selected cases within forty-eight hours of the attack. The hospital mortality is stated to be 60 per cent. in all cases.

IT is now fifty years since Dr. H. C. Sorby, F.R.S., of Sheffield, published the first of his long series of papers. The Literary and Philosophical Society of his native city have determined to celebrate the occasion by having his portrait painted, and have opened a subscription list for the purpose. The treasurer is Mr. A. T. Watson, Assay Offices, Leopold Street, Sheffield.

THE Ottawa correspondent of the *Times* states that reports have been received from Mr. William Ogilvie, a Government Surveyor, who is wintering on the Yukon, in which he speaks of gold discoveries on the tributaries of that river of almost incredible richness. Mr. Ogilvie has taken every means to verify the reports. On one stream three men had washed out 1200 dollars' worth in eight days. The gold-bearing belt is 300 miles long, and well within British territory.

DR. NANSEN delivered a lecture on his Arctic journey, on Saturday evening, at a meeting of the Berlin Geographical Society. After the lecture, it was announced that the Emperor had conferred on him the great gold medal for science and art, "the highest distinction which can be bestowed in Germany for peaceful achievements." Dr. Nansen also received the Humboldt gold medal of the Geographical Society, and was nominated an honorary member of the Society. On Sunday Dr. Nansen lunched with the Emperor at the Royal Castle.

THE British Consul at Chicago, in his report on the trade in his district for the past year, mentions that many goods of German make are finding their way into the Western States, and are taking the place of British goods. Amongst these are chemicals, quinine, ammonia, caustic soda, plate-glass, fuller's earth, Portland cement, cutlery, needles, surgical instruments, paints, and oils.

Science makes a strong protest against some vexatious provisions in the new Tariff Bill now before Congress. The Bill imposes a tax of 45 per cent. *ad valorem* on scientific apparatus "imported especially for colleges and other institutions"; it imposes a tax of 25 per cent. on books imported for public libraries, on books "printed in languages other than English," on books "printed more than twenty years," and on books "devoted to original scientific research"; and it imposes a tax of 25 per cent. on works of art. This simple statement shows that men of science in the United States have abundant cause for complaint against the Bill.

The Cairo correspondent of the *Times* reports that Prof. Forbes, the electrician, who has just returned from Wady Halfa, expresses a highly favourable opinion about utilising the power of the cataracts for generating electricity, and considers the general circumstances of Egypt exceptionally well adapted for its use as motive power. He thinks that the cataract power would be available all the year round for working the railway, cotton ginning mills, sugar factories, irrigation machines, &c., also that it could be supplied over distances of several hundred miles at a cost much below that of coal. Prof. Forbes is now on his way to England. He will return to Egypt in September next, to make a complete survey and present the Government with a project for utilising the electricity to be generated at the Nile cataracts.

The rapidity with which Röntgen photographs can now be taken was exemplified by a series of pictures recently shown by Dr. John Macintyre at the Glasgow Philosophical Society. Dr. Macintyre passed through a kinematograph a film thirty-five feet long, having upon it radiographs of a limb of a frog, and he was thus able to show distinctly to a large audience the movements of the bones in the limb. To obtain the photographs the kinematograph was covered with lead, in which there was the usual aperture. This aperture was covered with black paper. The tube was then put in the best condition, the mercury interrupter being used with a 10-inch spark coil. The movements of the limb of the frog were controlled by a mechanical arrangement.

A short time ago, one of our correspondents ("S. J. R.," Nature, vol. liv. p. 621) described the injurious effects of the X-rays on his hands. He is not the only one, however, that has suffered in this way: several other operators, who have been experimenting with these rays for any length of time, have had either to bear the consequences, or give up for a short time this line of work. An interesting summary and discussion of many of the well-recorded cases of dermatitis due to the X-rays, forms an article in the *Bulletin* of the Johns Hopkins Hospital. The writer, Mr. T. C. Gilchrist, after reviewing the several cases, finds that the X-rays are even more powerful than have been generally thought, and hat the deleterious effects may in some cases be quite serious; the cutaneous manifestations are not, however, the most severe of the lesions, but they are surpassed in severity by those of the deeper tissues, and particularly of periosteum and bones. The discovery of this deeper and more profound effect calls for a new explanation to account for the cutaneous lesions. It seems probable that, according to the writer, these injurious effects may be due to the platinum particles piercing the bulb, and then attacking the tissues. On clinical grounds, he states, there is considerable support for this, at first sight, improbable theory. If the lesion extends at all deeply, it leads to the formation of ulcers, which are extremely intractable, and they may be due to irritating particles still present in the tissues. Mr. Gilchrist advises X-ray operators and experimenters, who develop any special idiosyncrasy, to abstain from their use if they find that the slightest deleterious results follow an exposure to them.

A number of valuable works on botany and other branches of natural history, from the library of the late Mr. Freeman C. S. Roper, were sold by auction last week, the 668 lots realising a total of 1308*l.* 15*s.* Among the more important lots mentioned in the *Times*, with the prices obtained, are the following:—Mr. C. Cooke, "Illustrations of British Fungi," 1881-91, eight volumes, 17*l.* 5*s.*; "The Grete Herbal," printed at Southwarke by P. Treveris, 1526, extremely rare, a sound copy, 39*l.*; a set of the Ray Society publications from the commencement in 1845-1893, 28*l.*; P. A. Saccardo, "Sylloge Fungorum," 1882-96, 27*l.*; the *Journal of Botany* from its commencement in 1863 to 1896, 21*l.*; J. Sowerby, "English Botany," 1790-1863, with the Rev. M. J. Berkeley's appendix volume on British Algæ, 36*l.*; another of the same work, but the third edition, 1863-92, 15*l.* 10*s.*; "Bryologia Europæa," a work on mosses by Bruch, Schimper, and Gümbel, 1836-64, 18*l.* 5*s.*; *Transactions* of the Zoological Society, 1835-95, 43*l.* 10*s.*

The *Daily Chronicle* announces that the preliminary arrangements are now completed for laying across the English Channel two additional telephone cables. The first cable will be laid shortly by the English cable ship *Monarch*, the second being laid by the French Government, for whom it has been constructed in France. The cables will leave the English side of the Channel about three miles to the west of Dover. There are two circuits in each wire; so that, with the cable already laid, there will be six wires available for public use instead of two, as at present, which are in constant use. When the additional cables are duly installed, it is stated that facilities for international telephoning will be given to the large commercial centres in both England and France, instead of confining them to London and Paris only, as at present. When the two new cables are laid, there will be in all about thirty-four wires across the English Channel between St. Margaret's, Dover, on the east, and Beachy Head on the west.

Four hundred years ago the Atlantic was crossed for the first time by Cabot, and a little later Vasco da Gama started on his first voyage to India round the Cape of Good Hope. As the fourth centenary of these epoch-making expeditions will shortly be celebrated in Bristol, Canada and Portugal, an article upon them, by Mr. Edward Salmon, in the current number of the *Fortnightly Review*, appears at the right psychological moment. It is generally believed that Sebastian Cabot was the captain of the English ship which first touched the new continent, but attention is called to Mr. Henry Harrisse's work on "John and Sebastian Cabot," in which it is shown that Sebastian was an impostor who took credit for what his father, John Cabot, did. Furthermore, according to accepted opinion, Cabot struck land at the easternmost point of Cape Breton, but Mr. Harrisse concludes that the first point reached was Cape Chudleigh. John Cabot left Bristol for the voyage west in May 1497, with one small vessel and a crew of eighteen men; Vasco da Gama lef Lisbon, after elaborate preparations, on July 8 in the same year, in charge of three vessels. He arrived at Mozambique in March 1498, and went from there to Melinde. Leaving Melinde he proceeded across the Indian Ocean, and in three weeks arrived in India, whether off Calicut or Cananor is doubtful. A few other interesting points on the voyages of Cabot and Vasco da Gama will be found in Mr. Salmon's opportune article.

The latest issue of the *Izvestia* of the Russian Geographical Society (xxxii. 4) contains a very well-written account, by P. K. Kozloff, of the last portion of Roborovsky's Tibet expedition. While the main body of the expedition was returning from the Nan-shan Mountains, *viâ* Hami, to the Russian post of Zaisan, Kozloff made three very interesting side-journeys across East Tian Shan, and in the adjoining deserts. During one of those journeys he crossed the Kobbe sand desert, which was once visited by Prjevalsky, and lies in the Dzungarian depression, between East Tian Shan and the Altai. The wild camel, the wild horse (*Equus Przewalskii*), and the kulang still live in numbers in the Kobbe desert. As to man, only a few Kirghiz shepherds visit it. From these shepherds, as well as from the inhabitants of the Urungu valley, Kozloff heard about the wild men (*Kyz-kiyik*) who are said to live in that desert; and although the Russian explorer does not much trust to the rich fancy of the nomads, he nevertheless faithfully reproduces what

he has learned about the *Kyz-kiyiks* for the use of future explorers. The information runs as follows:—"The size of these men is not smaller than the habitual man's size. Their body is all covered with a short hair of the same colour as in the young camel, black hair falling on the shoulders, and dark eyes; body short and thin, legs relatively long. The *Kyz-kiyik* feeds on roots of plants growing along the streamlets in the sands; moves about in pairs; looks severe, harsh; emits sounds when he is dissatisfied with something, or as a calling signal. When he is pursued, he shouts loudly, and in his shout one hears a whistling sound. The wild man runs very swiftly and walks rapidly, setting his feet wide apart. The Kirghizes whom I spoke to said they had taken *Kyz-kiyiks* alive. The Kirghizes kept them for two or three days in their tents, and tried to feed them with meat and cakes, but they ate nothing; when forced to eat, crossed their hands on the breast, and twinkled with the eyes. They could not bear a steady look, turned the head aside, and on their own will made their hair stand on end. When they were set free, they took at once to the sands, and were joined each time by a comrade, who concealed himself, in the meantime, somewhere in the neighbourhood." The Kirghizes added that it would not be difficult to catch one of them in the winter, but not in summer, as they never have been seen in summer, probably because they conceal themselves in some inaccessible place.

THE opinion that distinct toxins require distinct anti-toxins would appear to require some modification. Dr. Calmette has shown that anti-venomous serum protects against scorpion poison; Roux and Calmette have shown that rabbits vaccinated against rabies, acquire remarkable powers of resisting the action of cobra venom. Again, animals vaccinated against tetanus and anthrax respectively, not only elaborate anti-tetanic and anti-anthrax serum, but such serums have also been found to be in some cases capable of counteracting the effects of cobra venom. Calmette has also shown that anti-diphtheria, anti-tetanus, anti-anthrax, and anti-cholera serums possess decided immunising powers with regard to the vegetable toxin of abrine. Dr. Memmo, working in the Hygienic Institute of the University of Rome, has observed that a distinct, although slight, curative action is produced by anti-diphtheria serum in cases of tetanus. Some extremely interesting investigations by Dr. Marriotti-Bianchi, dealing with the action of normal serums from various sources on different bacterial toxins, also tend to confirm the above observations. Bianchi has also been able to reproduce all the phenomena, claimed by Pfeiffer, to be specific in respect to the behaviour of cholera vibrios in anti-cholera serum, by placing these vibrios in normal serum derived from dogs and cats respectively. It would appear that not only may various anti-toxins modify one and the same toxin, but normal serums may also produce in some cases protection against toxins. This latter point has been specially dwelt upon by Bianchi in his memoir.

A PAPER by Mr. Walcot Gibson, published in the *Transactions* of the Federated Institute of Mining Engineers, will prove useful to all who wish to obtain a clear general notion of the geological structure of the continent of Africa. Written primarily from an economic point of view, a large portion of the paper is naturally devoted to South Africa, for which territory the author pleads the urgent necessity of a thorough geological survey. For the same reason, all beds later than the Karoo receive rather summary treatment, which the pure geologist will regret. The accompanying map, on the scale of about 400 miles to the inch, is very valuable: on it the author has indicated his views on the general correlation of beds throughout the continent. The frequent blanks and queries show how much has yet to be learned of the structure of Africa; but the continual discovery of new facts tends to rapidly throw a map out of date. Even since the preparation of this map, two important additions to our knowledge of African geology have been recorded in the *Geological Magazine*. Dr. Gregory has recorded (from the specimens collected by the Lort-Phillips expedition) the occurrence of Lower Jurassic (Bathonian) rocks, with an Indian fauna, in Somali-land, and has pointed out the bearing of this on the important question of the ancient union of India and Africa. More recently Mr. Draper has found nummulitic limestone on the coast of Gaza-land, and Mr. R. B. Newton, who has identified the nummulites, also records the presence of Upper Cretaceous fossils in the same area.

IN *Das Wetter* for February, Dr. W. Meinhardus, of Potsdam, discusses the possibility of predicting the general character of the weather for some time in advance, based upon the researches of Prof. O. Pettersson, of Stockholm, as to certain relations found to exist between hydrographical and meteorological phenomena. One of the questions dealt with by Prof. Pettersson, is whether the Gulf Stream, or its northern extension, brings the same amount of warmth yearly, or whether variations occur from year to year, and whether any connection exists between its variations and climatic conditions. With this object, he plotted the monthly means of air and sea temperatures for Norwegian stations for twenty years, and found the interesting result that the sea-surface temperature curves for the months December to April, and July to September, exhibit a similar course. A break in the continuity occurs in October and November, and again in May and June, which points to a decided change in the ocean currents at those seasons. The same characteristic is found to exist in the air-temperature in the inland parts of Sweden. From this correspondence of the air with the sea-temperature, and the continuity of the latter through whole groups of months, he concludes that it may be possible to foretell the general character of the weather for a long period in advance. If, for instance, certain conditions are found to exist in the sea-surface temperatures in December, an opinion may be formed of the coming winter and spring. Of course such predictions are quite distinct from those relating to current weather changes, which at present cannot be foretold for more than a day or so in advance. Dr. Meinhardus has extended this inquiry so as to include various stations in Germany, and has plotted the temperature means for thirty-five years. The results confirm those obtained by Prof. Pettersson in a very satisfactory manner. The probability of similar temperature changes in November and December at Christiansund, and in Hamburg, in the following quarter of the year, amounted to 85 per cent., while at inland stations a somewhat less, but still high percentage obtained.

THE address to the South London Entomological and Natural History Society, referred to in last week's NATURE (p. 515), was delivered by Mr. Richard South, the retiring president of the Society.

AN instructive paper on the geology of the Alps, recently read by Prof. T. G. Bonney before the Geologists' Association, appears in the March number of the Association's *Proceedings*. The title of the paper is "An Outline of the Petrology and Physical History of the Alps."

THE first number of a new journal, the *Zeitschrift für Criminal-Anthropologie*, has just appeared. The contents include articles on Lombroso and criminal anthropology of to-day, crime and mind disease, the handwriting of criminals, and a report on the proceedings of the fourth international congress of criminal anthropology, held last August at Geneva. There are also notes on current literature, and reviews of books which come within the scope of the journal. The general editor is Dr. Walter Wenge, and the publisher is A. Priber, Berlin.

Judging from the very interesting paper on "The First Crossing of Spitsbergen," in the April number of the *Geographical Journal*, Sir W. Martin Conway's forthcoming book will be an attractive as well as instructive contribution to geographical and geological literature. The general results of the expedition, of which Sir Martin Conway was the leader, have already been described in these columns (vol. liv. p. 437, 1896), and some idea will have been gained of their value from many points of view, particularly on account of the flood of light they throw upon vexed problems of glacial geology. Many remarkably fine illustrations of glaciers and moraines, and a large sketch map of part of Spitsbergen, accompany Sir Martin Conway's paper.

A memoir, by Mr. Alexander McAdie, on the "Equipment and Work of an Aero-physical Observatory," has been published as No. 1077 of the Smithsonian Miscellaneous Collections. The memoir was awarded honourable mention and a bronze medal, in the Hodgkins Fund Prize Competition. The subjects discussed are the known properties of atmospheric air considered in their relationships to research in every department of natural science, and the importance of a study of the atmosphere considered in view of these relationships. Mr. McAdie also points out the proper direction of future research in connection with the imperfections of our knowledge of atmospheric air, and the conditions of that knowledge with other sciences.

For the past eleven years Prof. H. G. Seeley, F.R.S., has, through the medium of the London Geological Field Class, done much to impart a practical knowledge of the physical geography and geology of the Thames district. Nature must be looked in the face if her character is to be understood; and it is to give students an opportunity of thus viewing her directly, while her physiognomy is read, that the Class was founded. The teaching is given by Prof. Seeley during excursions made on Saturday afternoons, between the beginning of May and the middle of July. The twelfth annual course will commence on May 1, with an excursion to Leith Hill. Particulars of this and other excursions may be obtained from the honorary secretary, Mr. R. Herbert Bentley, 43 Gloucester Road, Brownswood Park, South Hornsey, N. All London students of the elements of geology should take advantage of the systematic course of teaching in the open country offered by the London Geological Field Class.

Mr. S. G. Newth, of the Royal College of Science, has invented a little instrument for use in the detection of potassium compounds by the flame test, in the place of the indigo prism. Owing to the fact that indigo transmits the red rays given by lithium, strontium, calcium and barium compounds, as well as the red of potassium, salts of those metals, when heated in a Bunsen, while the flame is examined with an indigo prism, are mistaken for those of potassium. Mr. Newth's instrument, however, not only absorbs the green and yellow portions of the spectrum, but also the red, very nearly as far down as the potassium line, and quite beyond the red lines of lithium, strontium, calcium and barium. It is therefore opaque to the red light given by these metals, while being transparent to the red light of potassium; and it thus allows of the certain detection of potassium in the presence of any of these metals, or of sodium. A patent has been applied for, and the instrument will shortly be put on the market.

New editions have been received of the following works:—Bourne's Insurance Directory, by William Schooling (London: Effingham Wilson). This trustworthy and valuable statement of the positions of insurance companies, and their comparative advantages, should be seen by all who are interested in assurance or actuarial affairs.—"Appearance and Reality: a Metaphysical Essay," by Dr. F. H. Bradley. Second edition. (London: Swan Sonnenschein and Co.). The author describes his work as "a more or less desultory handling of perhaps the chief questions in metaphysics. . . . This volume is meant to be a critical discussion of first principles, and its object is to stimulate inquiry and doubt."—"Les Femmes dans la Science," by A. Rebière. Second enlarged and revised edition. (Paris: Libraire Nony and Co.). The first edition of this book was reviewed in Nature of July 19, 1894 (vol. l. p. 279). Many new names have been added, and some, perhaps, have been inserted without sufficient discrimination; while the information about several of the ladies whose names adorn the pages is often very meagre. The book now includes the names of women who may be termed scientific amateurs, *collaboratrices*, and *protectrices*, as well as of genuine workers. Notwithstanding this, the volume is an interesting monument to the genius of women; and the portraits and autograph letters add to its attractiveness.

The valuable work carried on under the direction of Prof. S. A. Forbes, upon the Illinois River and its dependent waters, has often been noted in these columns. The general object of the biological experiment station of the University of Illinois is to study the forms of life, both animal and vegetable, in all of their stages, of a great river system, as represented in carefully selected localities. How well this object has been attained may be seen from the Biennial Report just received, together with various bulletins of the Illinois State Laboratory of Natural History containing accounts of zoological investigations made at the station. The publications amount in all to some three hundred pages of text, with sixty plates. In one of the papers Dr. C. A. Kofoid describes in detail the methods and apparatus used in "plankton" observations at the station. This term is applied to all plants and animals floating free in water, and incapable by their own efforts of materially changing their position. Prof. Frank Smith has devoted particular attention to a study of oligochæte worms (earthworms and their allies) found in and about the Illinois River and other waters near Havana. The collections made comprise about thirty species, several of which are new. A full report upon the Oligochæta is in preparation. In a valuable contribution, Mr. C. A. Hart gives an account of observations of the insect fauna of the Illinois River and adjoining waters; his paper fills one hundred and twenty-five pages, and, as an example of work done during the first year of the station's establishment, it is very creditable. Mr. Adolph Hempel describes new species of Rotifera and Protozoa. About ninety species of Rotifera and eighty species of Protozoa have been collected upon the Illinois River. Among the Rotifera there are three presumably hitherto undescribed species of the genus Brachionus. From the papers we have named, it will be evident that the Biological Experiment Station of the University of Illinois has more than justified its existence. If evidence is needed in support of the scheme for the establishment of freshwater biological stations in Great Britain, it will be found in the papers to which reference has been made.

The reaction of ferric chloride, potassium chlorate and hydrochloric acid, has been carefully investigated by Messrs. Noyes and Wason, whose results are published in the current number of the *Zeitschrift für physikalische Chemie*. The change is of special interest, because it is the first satisfactory case of a reaction of the third order in which three different substances are concerned. Hood had previously stated that in presence of excess of acid the reaction is of the second order, its velocity being proportional to the product of the concentrations of the ferrous chloride and of the potassium chlorate. When the concentration of the hydrochloric acid is varied it is seen, however, as the authors show, that the reaction is really of the third order, and that its velocity is proportional to

the product of the concentrations of all three substances. Without making assumptions, the truth of which cannot at present be verified, it is impossible to represent the reaction by means of a chemical equation, in which the change takes place between three molecules only. Like many other reactions, it is of a lower order than would be the case if the order were determined by the number of molecules represent ed by the chemical equation as taking part in it. The cause of this simplicity remains at present unknown. The influence of temperature on the velocity of change is well represented by Van 't Hoff's well-known equation ("Études," p. 115). An increase of temperature from 0° to 10° C. increases the velocity 2·7 times; all other reactions, so far studied, are influenced to much the same extent, the effect of a rise of temperature of 10° being to increase the velocity from 2 to 3·6 times; the average number is 2·8.

THE additions to the Zoological Society's Gardens during the past week include two Californian Quails (*Callipepla californica*, ♂ ♀) from California, presented by Mr. T. M. Howells; a Black-headed Lemur (*Lemur brunneus*), a Madagascar Boa (*Boa madagascariensis*) from Madagascar, a Canarian Pigeon (*Columba laurivora*) from the Canary Islands, deposited; two Black-necked Storks (*Xenorhynchus australis*) from Malacca, two Larger Tree Ducks (*Dendrocygna major*) from India, a Ruddy Sheldrake (*Tadorna casarca*, ♂), four Tufted Ducks (*Fuligula cristata*), European, purchased.

OUR ASTRONOMICAL COLUMN.

MR. ISAAC ROBERTS ON LONG-EXPOSURE PHOTOGRAPHS.—In the current number of *Knowledge*, Mr. Isaac Roberts describes a beautiful photograph of Orion, taken by him with an exposure of seven hours thirty-five minutes, the photograph "depicting very probably the maximum of extent and detail that can be shown by aid of photographic methods." This statement, coming from one so versed in celestial photography, cannot be considered lightly, but must be carefully weighed before judgment be given. The reasons which Dr. Roberts gives for this statement are as follows: (1) The film of the negative is, in consequence of prolonged exposure to the latent sky luminosity, darkened on development to a degree that would obscure faint nebulosity and faint stars. (2) Longer exposures of the plates would not reveal additional details of nebulosity, nor more faint star images. Dr. Roberts goes on to say that, although he has taken all precautions to protect the plates from extraneous light, to photograph only on clear evenings, &c., yet the longer the exposure the darker the film becomes in the development of the images. The sequence, he states further, has been observed for many years on all very sensitive films which have had long exposure, and the results have been practically invariable. An important point, favouring Dr. Roberts' statement, is that the unexposed margins of the films do not undergo this process of being darkened, but remain perfectly clear. The point raised by him is one well worth consideration in these days of long exposures; and although the evidence he brings together is strong, yet we hope he has not proved his case.

VANADIUM IN SCANDINAVIAN RUTILE.—For producing the spectrum of titanium, Prof. B. Hasselberg used titanic acid in the form of rutile in the electric arc, finding that it was more suitable than commercial titanium. This rutile came from Krageröe, in Norway, its other chief component, besides titanic acid, being oxide of iron, in a quantity of about 1 or 2 per cent. The spectrum obtained from this substance, after the elimination of known impurities, was thought at first to be pure titanium, but it was found "that among the fainter and faintest lines of my titanium spectrum there are several that doubtless belong to *vanadium*." A re-examination of a large piece of the latter, and subsequent comparison photographs of vanadium and rutile, exhibited many striking similarities. Another kind of rutile was put to the same test. This was Swedish rutile from Käringbricka, in Westmanland, which contained chromium in addition. A comparison photograph of the spectra showed that the same series of coincidences was found as in the case of the Norwegian rutile, as Prof. Hasselberg shows in the table of his results, given in the *Astrophysical Journal* for March (No. 3). Further spectroscopic experiments suggested that the Swedish variety contained a greater amount of vanadium than the Norwegian; but whether the difference is sufficient to be recognised, or determined quantitatively chemically, remains uncertain.

COLUMBIA UNIVERSITY OBSERVATORY'S PUBLICATIONS.—In the two numbers (10 and 11) of the Contributions of this Observatory, Prof. Harold Jacoby presents two communications on (1) the reduction of stellar photographs with special reference to the Astro-photographic Catalogue plates, and (2) on the permanence of the Rutherfurd photographic plates. The first paper has been written at the request of Dr. Gill, who asked him to put together the formulæ which seemed best for the reduction of the Astro-photographic Catalogue plates. Prof. Jacoby acknowledges the work of others on the subject, and the method he gives is suitable for the reduction of any photographic plates, whether the programme of the Permanent Committee has been adopted or not. The only restrictions are that the centre of the plate must be more than 15° from the pole, and that the plate does not cover more than two square degrees. A description of the method would be too long to give here, so we will confine ourselves to the statement that Prof. Jacoby's formulæ greatly facilitate the computation as a whole. As an illustration of the method of reduction, he gives a fully worked-out example of a plate taken at Paris in 1891, and discussed by M. Prosper Henry. The second communication, dealing with the permanence of the Rutherfurd plates, gives the results of a comparison of the old measures of the Pleiades and those quite recently completed. The object of the investigation was to test the durability of the photographic film, and see whether any deformation, either contraction or expansion, had occurred in the interval since the first measurement, made nearly a quarter of a century ago. The question is one of great importance, since some of Rutherfurd's photographs are still unmeasured; it has, further, a great bearing on the plates of the astro-photographic chart of the heavens. The result of the investigation can be best illustrated by extracting from the final table the figures representing the differences between the old and new measures as obtained from three separate plates. These are as follows:—

Rutherfurd Measures minus New Measures.

Star.	Plate 16.		Plate 18.		Plate 22.	
	Angle.	Dist.	Angle.	Dist.	Angle.	Dist.
	"	"	"	"	"	"
A 34	0·00	−0·12	−0·24	−0·21	+0·07	+0·26
18*m*	− ·06	− ·06	+ ·12	+ ·05	− ·08	− ·34
A 12	− ·01	− ·18	+ ·40	+ ·14	+ ·16	− ·10
A 22	− ·04	+ ·27	− ·06	− ·08	− ·06	+ ·19
A 24	− ·02	+ ·16	·00	+ ·30	− ·13	+ ·10
A 28	+ ·08	− ·10	+ ·18	− ·13	− ·12	− ·13
A 30	− ·02	− ·01	− ·45	+ ·08	+ ·17	− ·01
A 39	+ ·41	+ ·03	+ ·14	− ·18	+ ·39	+ ·02

The conclusions that can be drawn from the whole discussion are that the positions of the individual stars on the plates may be practically determined from either set of measures, the mean error amounting to about 0".1. Thus the new measures will furnish practically identical results with those that would have been obtained if the plates had been measured twenty years earlier.

A GIFT TO THE PARIS ACADEMY OF SCIENCES.

THE Paris correspondent of the *Times*, writing under date April 5, makes the following announcement:—

M. Berthelot read this afternoon, at the Academy of Sciences, the following letter addressed to him in French by Mr. H. Wilde,

president of the Manchester Literary and Philosophical Society, announcing to the Academy the gift of 5500*l.* to be set apart for an annual prize of 400of. I send you the original letter, without undertaking, considering its special and technical character, to translate it :—

Diverses considérations m'engagent actuellement à me mettre en communication avec l'Académie dans le but de stimuler de nouvelles investigations dans les sciences physico-chimiques, et de faire disparaître quelques-uns des obstacles qui entravent leurs progrès. L'un de ces obstacles qui appelle la sérieuse attention des penseurs philosophes est l'invasion d'une autorité dogmatique dans une science scolastique, pour soutenir des erreurs démontrées et des méthodes erronées d'observation et d'expérience. Il sera suffisant pour l'objet que j'ai actuellement en vue de citer le système périodique des éléments chimiques comme un exemple de l'abus d'autorité dans une branche de la science où vous occupez un rang si distingué. J'ai à vous exprimer mes regrets que vos vues au sujet de la prétendue loi périodique ne soient venues que récemment à ma connaissance ; sans cela je m'y serais référé dans mes travaux généraux sur les relations numériques des poids atomiques. Quoique vous ayez clairement indiqué, monsieur, dans vos "Origines de l'Alchimie," les sophismes et les contradictions inhérents à ce système, et que vous ayez également montré que la prédiction de l'existence et des propriétés des éléments inconnus n'a aucune relation nécessaire avec la prétendue loi périodique, cependant ce système a depuis été imposé aux personnes qui s'occupent de science par les sociétés scientifiques et les corps enseignants comme une vérité naturelle d'une autorité indiscutable.

Je n'ai pas besoin de vous rappeler que l'état actuel de la chimie théorique en raison de la connaissance formelle de ce dogme est réellement déplorable. Les savants qui aspirent à se distinguer dans la chimie et dans la physique estiment qu'il est nécessaire de donner des preuves de leur croyance personnelle, en tâchant de montrer la corrélation de leurs propres travaux sur des points particuliers avec le système périodique, et ils évitent toute référence aux proportions multiples des poids atomiques, comme à une dangereuse hérésie. Beaucoup de ces néophytes, de même que certains auteurs de manuels, ne peuvent se faire une idée, ou ignorent la signification de l'idée de la périodicité telle qu'elle est définie par De Chancourtois, Newlands et Mendeleief dans leurs mémoires respectifs. Ils appliquent l'expression impropre de loi périodique à la progression de propriétés antérieurement connues observables dans les familles naturelles des éléments, à la corrélation avec les poids atomiques de propriétés physiques et chimiques établies depuis longtemps, à la progression bien connue des propriétés physiques dans les séries homologues des composés organiques. Par suite, le danger pour les progrès futurs de la chimie théorique est que, lorsque l'idée illusoire d'une spiro-périodicité des propriétés analogues des éléments sera universellement abandonnée, le nom impropre de loi périodique est exposé à prendre dans la science un caractère narasite de la même façon que cette autre expression impropre, "esprit lunatique," avec ses dérivés, subsiste encore dans la civilisation moderne comme une survivance de la physiologie mentale barbare des âges passés.

Heureusement pour l'avenir de la philosophie chimique que l'esprit de Dumas vit encore dans les esprits de la plupart des chimistes français, qui ne reconnaissent aucune autre autorité que la vérité de la nature telle qu'elle se présente à l'entendement, et qu'ils sont par là exempts de l'illusion de la prétendue loi périodique. En reconnaissance des nombreux profits que j'ai retirés de la science française, tant pure qu'appliquée, j'ai l'honneur d'offrir à l'Académie la somme de 5500*l.* (137,500f.) pour être placée en rente française, et l'intérêt provenant de cette somme devra être appliqué à la fondation d'un prix de 400of. à décerner tous les ans à l'auteur d'une découverte ou d'un ouvrage quelconque en astronomie, physique, chimie, minéralogie, géologie, et mécanique, qui, au jugement de l'Académie, sera jugé le plus méritant. L'attribution de ce prix sera internationale et pourra être retrospective.

Alderley Edge, Cheshire, 15 Mars, 1897.

The gift has given great satisfaction at the Academy, and is as much to the honour of the donor as to that of the distinguished secretary of that Academy, whose work is referred to in such terms of gratitude.

THE THEORY OF OSMOTIC PRESSURE.[1]

As osmotic theory is now attracting general attention in this country, it seems desirable that all the positions that are maintained in regard to it should be clearly set forth. The excuse for offering the following remarks is that for some time I have paid attention to the subject in its relations to general molecular theory, both in the thermal and the electrical aspects. I fail to recognise how the validity of the thermodynamic basis of the law of osmotic pressure can be shaken ; and though the idea of ionic dissociation in solutions is an additional hypothesis which must be judged separately by the extent of its agreement with the facts, it appears to me that in some form—possibly not at all in the chemical imagery with which it is at present often associated—it holds the field. It is difficult, in fact, to see how the hypothesis that the same chemical element can have different valencies in different series of compounds, which is now usually accepted, is fundamentally any whit less parodoxical than the hypothesis of ionic dissociation ; anything that throws light on the one must also illuminate the other.

In his recent note on this subject, Lord Kelvin[2] appears to allow, within certain limits, the cogency of the argument which bases the law of osmotic pressures on Henry's empirical law of solubility for gases ; an argument which has recently been carefully re-stated by Lord Rayleigh, having previously been employed, as he remarks, in forms more or less explicit, by van 't Hoff, Nernst, and other investigators. The connection thus established, however, hardly amounts to a physical demonstration, because it only deduces one empirical relation from another. Yet it seems desirable to draw attention to the fact, which I have not seen anywhere remarked, that this method had been employed by von Helmholtz in 1883, some time before van 't Hoff announced his theory of the correlation between osmotic and gaseous pressures ; and that the principles given by him in an investigation of the work-equivalent of gaseous solution, made in connection with the theory of galvanic polarisation,[3] involve in fact an implicit prediction of the osmotic law. This circumstance, that the law of osmotic pressure as regards dissolved gases is tacitly involved in von Helmholtz's equations, does not, of course, confer on him a position in the actual development of the subject.

But the theory of osmotic pressure can, I think, be placed on a purely abstract basis, independently of the law of solubility of gases, which would then assume the form of a deduction from it. The broad principles on which this is to be done have been in fact laid down, in a precise but very general manner, and without special applications, by Willard Gibbs as early as 1875, in his fundamental development of the laws of mechanical availability of energy.[4] The following position is, I believe, sound. Each molecule of the dissolved substance forms for itself a *nidus* in the solvent ; that is, it sensibly influences the molecules around it up to a certain minute distance, so as to form a loosely-connected complex, in the sense not of chemical union but of physical influence. The laws of this mutual molecular influence are unknown, possibly unknowable ; but provided the solution is so dilute that each such complex is, for very much the greater part of the time, out of range of the influence of the other complexes (as, for instance, are the separate molecules of a free gas), then the principles of thermodynamics necessitate the osmotic laws. It does not matter whether the nucleus of the complex is a single molecule, or a group of molecules, or the entity that is called an ion ; the pressure phenomena are determined merely by the number of complexes per unit volume.

To determine the osmotic forces, we must know the change in *available* energy that is involved in dilution of the solution by further transpiration of the pure solvent into it. In finding that change, the laws of mutual action between molecules of the dissolved substance are not required ; for there is actually no action between them, and as soon as the solution becomes so concentrated that such mutual action between the complexes comes in, the theory is no longer exact. Nor are the laws of mutual action between the molecules of the dissolved substance and

[1] Read before the Cambridge Philosophical Society, January 25, by J. Larmor, F.R.S.

[3] H. von Helmholtz, "Zur Thermodynamik Chemischer Vorgänge, iii." in Collected Papers, vol. iii. pp. 105–114, especially his equation (4) and the theory of diffusion at the end. [The theory had already been given explicitly in 1876 by Willard Gibbs, *loc. cit. infra*, p. 227.]

[4] *Trans.* Connecticut Academy, November 1875, p. 138 : "Effect of a Diaphragm Equilibrium of Osmotic Forces)."

those of the solvent required, because the effect of transpiration of more of the solvent into the solution is not in any way to alter the individual complexes. The change in available energy of the system, on dilution, thus solely arises from the expansion of the complexes into a larger volume; and it can be traced into exact correlation with the change of available energy that occurs in the expansion of a gas. This argument meets the objection that a true theory should involve a knowledge of the molecular actions between the various molecules. It would seem that with just the same cogency it might be argued that a real investigation of the connection of the alteration of the freezing-point of a liquid by pressure, and its change of volume on freezing, should involve a knowledge of the individual molecular actions in the liquid; and so it would, had we not the means of evading molecular considerations that is afforded by Lord Kelvin's great principle of availability, which is for this very reason at the basis of all physical theory.

There is, however, one point to be remembered, namely, that the theoretical osmotic pressure is a limiting value which may not be reached by an actual arrangement, unless we can be certain that it works reversibly, and so without heating effects.

The remark has been made by Lord Kelvin, that the connection between Henry's law and the osmotic law must break down when the solution of the gas is accompanied by change in its state of molecular aggregation. It is also probable, from the fundamental ideas as to dissociation and aggregation, that such change would usually be partial, and not uniform over all the dissolved molecules; so that it is not to be expected that Henry's law would, in such circumstances, hold good. The point in which the argument, as set forth in precise form by Lord Rayleigh (Nature, *loc. cit.* p. 254), becomes then inapplicable, is that the gas expelled from solution by the osmotic process must be considered as emerging in the actual state of aggregation differing from that of its free condition, and its return to the latter state involves further change of available energy.

If the considerations above stated, which will be most suitably developed in detail in another connection, are valid, it follows that Prof. Poynting's recent suggestion (*Phil. Mag.*, October 1896), with a view to evading the necessity of the ionic dissociation hypothesis, cannot avail, as it would not lead to the desired value for the osmotic pressure; that pressure depends on the number of molecular complexes involving the dissolved substance, that exist in the dilute solution, but not on their individual degrees of complexity.

THE OSTRICH.[1]

THE ostrich, *Struthio camelus*, has been observed with interest from very early times; it has frequently been the subject of remark by African travellers; and it has been domesticated and farmed in the Cape Colony for some thirty years. Yet it is remarkable how little is known about it in scientific circles, and how many misconceptions still prevail as to its nature and habits.

This article is founded on personal observations made during nine years of uninterrupted ostrich-farming in the Karroo of the Cape Colony, and during travels about the country generally. In large ostrich camps, some of which are a couple of miles in diameter, numbers of birds of both sexes run in what is practically a wild state, seldom interfered with in any way, except when rounded up to be plucked or to be fed in a drought. The habits of birds thus farmed differ in no way from those of native wild birds, except perhaps that monogamy is more difficult.

Number of Species.

All the differences on which the arguments for classifying the ostrich into three species are founded, are commonly present among the ostriches of the Cape Colony—that is, of South Africa generally; for a great many of the Cape ostriches are the progeny of birds brought down from "The Interior"—the Kalahari Desert, Damaraland, and beyond. There is, I think, little doubt that all South African ostriches are of one species; individual variations, accentuated by local differences of food and climate, are quite sufficient to account for all supposed varieties. I do not think that, on the evidence which I have been able to gather, there is any justification for maintaining that there is more than one species of ostrich.

The Egg of the Ostrich.

The ostrich hen lays every other day, and the egg weighs about three pounds; it is a tasty and nutritious food however prepared, very rich, and excellent for making pastry and cakes. It is generally computed to be equal to two dozen fowls' eggs; but this must be on account of its superior richness, for, from personal experiment, the empty shell of a fairly large one exactly held the contents of eighteen fowls' eggs. It takes about forty minutes to boil an ostrich egg hard. The period of incubation is about six weeks.

Leaping and Swimming.

The old idea that an ostrich can only leap over a very low fence, or across but the narrowest sluit (gully), is incorrect. The birds will, when startled (never deliberately), sometimes go over a six-strand wire fence nearly five feet high, putting one foot on one of the middle wires, and striding over with the other. They will go over a stone wall in the same manner, if too high for them to step upon; and I have seen a cock take a standing jump on to the top of a wall five feet high, beyond which were his chicks.

Even as a chick the ostrich is a powerful swimmer. I have known several birds swim some distance down the Great Fish River when it was running fairly strong, and have heard, on what seems trustworthy evidence, of a cock that was carried a long way down the same river when it was running nearly level with its precipitous banks in the stormy season; he was some hours in the water before he could get out, but emerged unhurt.

How it Feeds, and what it will Swallow.

The ostrich feeds in a peculiar manner. It tosses the food into a sack in the upper part of the neck, and then swallows it. I have seen a bird toss fully a quart of mealies (Indian corn) into this sack before swallowing; and it is no uncommon thing to see two "swallows" travelling down the neck at the same time with a clear interval between them; or to see one of them (if of large and loose food, *e.g.* grain) slide back into the sack after being swallowed, if the bird lowers its head to continue feeding before the food has travelled some considerable distance down the neck. The food travels slowly, and performs a complete circuit of the neck before reaching the crop. Crushed bones are greedily eaten; if too large a piece should stick in the neck, it is a simple matter to cut it out and sew the wound up again. The wound, as a rule, heals quickly, and causes but little inconvenience. As is well known, ostriches will swallow almost anything small enough to pass down the neck. An ostrich's crop always contains a large quantity of smooth stones, many of them brightly coloured.

How the Ostrich Runs.

Considerable misconception prevails as to the manner in which the ostrich runs. It seems to be still generally held that, when running, it spreads out its wings, and, aided by them, skims lightly over the ground. This is not correct.

When a bird really settles itself to run it holds its head lower than usual, and a little forward, with a deep loop in the neck. The neck vibrates sinuously, but the head remains steady, thus enabling the bird, even at top speed, to look around with unshaken glance in any direction. The wings lie along the sides about on a level with, or a little higher than, the back, and are held loosely just free of the plunging "thigh." There is no attempt to hold them extended, or to derive any assistance from them as organs of flight.

When an ostrich, after a long run, is very tired, its wings sometimes droop; this is due to exhaustion; they are never, by a running bird exerting itself to the utmost, held out away from the sides to lighten its weight or to increase its pace. But the wings appear to be of great service in turning, enabling the bird to double abruptly even when going at top speed.

The Nest.

As the breeding season approaches, a cock and hen will pair, and, having selected a site congenial to their inclinations,

[1] Abridged from a long article, by S. C. Cronwright Schreiner, in the March number of *The Zoologist*.

proceed to make a nest. I believe that in all cases, in the first instance, one cock and one hen, having paired, select the site and make the nest.

The nest is simply a hollow depression, more or less deep according to the nature of the soil. It is made by the pair together. The cock goes down on to his breast, scraping or kicking the sand out backwards with his feet, cutting the earth with his long and powerful nails. The hen stands by, often fluttering and clicking her wings, and helps by picking up the sand with her beak, and dropping it irregularly near the edge of the growing depression.

Laying and Sitting.

When satisfied with their work (and they are easily satisfied, often too easily) the hen begins to lay an egg in the nest, every other day. During the laying period the nest is often unattended, and is not slept on at night. A nest in which only one hen is laying contains on the average about fifteen eggs; but she often begins to sit before she has laid her full complement. Sometimes she will lay four or five after beginning to sit, though not often so many; sometimes only one or two; while sometimes she will lay her full complement. The hen generally begins the sitting; she will occasionally sit for one or two days and nights before the cock takes his turn. When sitting assumes its regular course, the hen sits from 8 or 9 a.m. to about 4 p.m., and the cock from 4 p.m. to about 8 or 9 a.m. The bird whose turn it is to be on the nest keeps its seat until the other arrives to relieve it, when they at once change places.

It is quite incorrect to say that the cock alone sits, or that during the day the eggs are left to the heat of the sun. The cock and hen sit alternately, regularly and steadily, night and day, during the whole period of incubation.

Protective Colouration.

The colour of each is admirably adapted to the time spent on the nest, and furnish interesting examples of protective colouration. It is scarcely possible to conceive a more effective disguise than the sober brownish grey of the hen for day sitting, and the black of the cock for night. When on the nest, the ostrich lays its head, neck, and tail flat along the ground; its naked "thighs" are covered by the wings, the plumes lying close together on the earth almost hidden against the bird's body. Thus only the low, long-curved body projects above the surrounding level. The cock, at night, is, of course, almost perfectly hidden; while the hen, at day-time, closely resembles a stone, bush, ant-heap, or any little inequality of the veld. One is surprised to see how close such a large bird can lie to the ground, and how even an ostrich-farmer may almost walk over a sitting hen in full daylight without seeing her. The cock is simply indistinguishable at night, except to a practised eye, and then only at a few yards distance.

Is the Ostrich Polygamous?

Every authority that I have consulted holds that the ostrich is polygamous, but the evidence against polygamy is very strong: a pair make the nest; the hen lays all her eggs (a full sitting) in that nest; the hatching of the eggs and the care of the chicks are shared equally by cock and hen; the cock loses his sexual vigour and ceases his attentions to the hen, soon after beginning to sit; and one hen to a nest yields the best results.

I do not, however, think it can be maintained that the monogamy of the ostrich is proved absolutely, but I decidedly think that the arguments in its favour are much stronger than those in support of polygamy.

Curious and Exceptional Relations.

Finally, it must be allowed that, while all the facts at my command point strongly to the conclusion that the ostrich is not only often monogamous, but that monogamy is the only condition perfectly favourable to the successful hatching and rearing of young; and that all the arguments in favour of polygamy break down on examination: yet the fact remains that there are a large number of curious and exceptional circumstances connected with the nidification, sexual relations, and parental habits of ostriches that I am not yet exactly able to account for, either on the supposition of fully organised monogamy or polygamy.

NATIONAL MEMORIAL TO JENNER.

THE meeting held on Wednesday, in last week, gave coherence to the scheme for raising a national memorial to Edward Jenner, in celebration of the centenary of the discovery of vaccination. "It was surely high time," said the Duke of Westminster, who presided over the meeting, "that this his native land should rise to the occasion, and at last, after 101 years have passed since the first successful vaccination, take active and effective steps to carefully preserve his great legacy to the world, and to do more—to give every facility for the promotion of science in the direction of the prevention of diseases that afflict mankind." Lord Herschell, in moving the first resolution—"That the present is an appropriate time to inaugurate a work of national utility in honour of Edward Jenner," pointed out that Jenner was the first to illustrate a principle which seemed destined to play an important part in the history of preventive medicine. Surely this alone is a high tribute to Jenner and the value of his discovery. His name is held in reverence by the highest men of science and the most civilised countries in the world. Some of these countries have already commemorated his centenary. Are Englishmen to be behindhand in testifying their admiration of the man, and their sense of the benefits he has conferred on humanity? The resolution was seconded by Prof. Michael Foster, who gave instances of the extension of the Jennerian principle to other diseases by Pasteur and other observers. Sir Alfred Lyall, in supporting the resolution, referred especially to the blessings which vaccination had already conferred upon the people of India. The resolution was then carried unanimously.

Lord Lister moved the next resolution:—"That a subscription be set on foot with a view of promoting, in connection with the British Institute of Preventive Medicine, but in a manner distinguished by Jenner's name, researches on the lines which he initiated." In speaking to the resolution (reports the *British Medical Journal*), Lord Lister referred to a mistake in his address to the British Association at Liverpool. The statement was to the effect that smallpox was unknown in the German army as a result of the revaccination of all recruits. If he had stated that fatal smallpox was absolutely unknown in the German army, it would have been the literal truth. A recent instance of the application of the principle discovered by Jenner was Dr. Koch's discovery that by using the bile of an animal which had died of rinderpest to inoculate a healthy animal, that animal was rendered immune to the pestilence for some months at least, time could alone decide for how long. This was an exact parallel to the discovery of Jenner, and the simplicity of the method was such that it places in the hands of any farmer the possibility of protecting the whole of his herd on the appearance of the first case. Another example was the work now being done in India with regard to plague. Two such examples, both taken from a period so recent, and so brief, were sufficient to prove the practical importance of work of this kind. And it was such work which the British Institute of Preventive Medicine was doing. That Institute had been the first in this country to supply the diphtheria antitoxic serum, the use of which had effected so remarkable a reduction in the mortality of the disease in those cases in which it could be employed early. The Institute had never ceased to improve the serum, until that which was issued now had six times the curative power of that first employed. The Institute also prepared tuberculin, which was capable of rendering such important services to the public health by facilitating the early diagnosis of tuberculosis in cattle; and mallein, which rendered similar services in the case of glanders. The Institute might claim, therefore, to be a work of utility, and it was a national institution, for it had upon its governing body representatives of public bodies in all three kingdoms. Thanks to the generosity of their Chairman, the Institute was in possession of a site upon which, owing also in part to his generosity, it had now nearly completed the erection of a suitable building for carrying on its work. But its income was only some 700*l.* a year; the scope of its work was thus cramped, its officers, who gave their services in the true spirit of scientific devotion, were inadequately remunerated, and, unless a large measure of public support was accorded, the full benefits which the Institute was capable of rendering to the country could not be realised. If the response to the movement inaugurated by that meeting was as liberal as it should be, the Council of the Institute were prepared to agree that its name should be changed to that of the "Jenner Institute." If the response were less generous, they might still hope that the sum received would be sufficient to

found a Jenner professorship of bacteriology, and in addition, or as an alternative, of a Jenner scholarship.

The resolution having been briefly seconded by Lord Davey, and supported by Mr. Brudenell Carter, was put to the meeting and carried unanimously.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

OXFORD.—Mr. H. M. Vernon, of Merton College, has been elected Radcliffe Travelling Fellow for the year 1897. Mr. Vernon took a first class in the Natural Science School in 1891.

EX-MAYOR WILLIAM R. GRACE, of New York City, and his wife and daughter have given two million dollars to establish in that city a school of manual training for women and girls.

THE first Huxley medal and prize of 10*l.*, open to students of the Charing Cross Hospital Medical School at the end of their second winter session, has been awarded to Mr. Arthur Gentry Pitts. The awards were founded last year, in memory of the late Prof. Huxley—a former student of the school.

IT has been decided that the memorial to the late Rev. William Rogers shall take the form of a physical laboratory, to be erected and fitted up in connection with the Charterhouse Schools, which were inaugurated by the Prince Consort, and were the first schools with which Mr. Rogers was connected on his entry into parochial work in London.

THE state of chemical industries in Germany, France and England, and the position of chemistry in higher education, forms the subject of an article, by M. M. A. Haller, in the *Revue Générale des Sciences* for March 30. Referring to the efforts which are made in this country to obtain a fuller recognition of the value of chemistry to manufactures, the author says: "Industriels et Professeurs prennent part à cette campagne, sans que les pouvoirs publics s'émeuvent." It is this lack of interest shown in scientific matters by State authorities that astonishes men of science on the continent.

BY the will of the late Mr. John Crerar, of Chicago, who died October 19, 1889, the residue of his estate, after the payment of numerous bequests, both private and public, was given for the creation and endowment of a free public library, to be called the John Crerar Library, and to be situated in the city of Chicago. Having sympathetically reviewed the library section of John Crerar's monumental will, and carefully considered the library facilities and needs of the city, the directors unanimously decided to establish a free public reference library of scientific literature. This library was opened on April 1. Its special field is that of the natural, the physical, and the social sciences, with their applications, the adopted classification being into general works, social sciences, physical sciences, natural sciences, applied sciences. The directors propose, however, to make the library exceptionally rich in scientific periodicals, American and foreign. The total endowment is estimated to be over 2,500,000 dollars, and the income should be sufficient ultimately to allow the making of a good collection within the proposed limits. At present the library has 15,000 volumes ready for use, and nearly 7000 more in process of preparation. The number of periodicals in the reading-room is 800, with 400 others to be added. By the end of 1898 it is expected that there will be 40,000 volumes on the shelves.

THE following are among recent announcements:—Dr. A. F. Dixon, senior demonstrator of anatomy at the School of Medicine of Dublin University, to be professor of anatomy at the University College of South Wales and Monmouthshire, Cardiff, in succession to Prof. A. W. Hughes, now professor of anatomy in King's College, London; Dr. Classen, of the Polytechnic Institute at Aachen, to be professor of chemistry in the University at Kiel; Dr. A. Palladin to be professor of plant anatomy and physiology at the University of Warsaw; Dr. de Vries to be professor of geometry in the University of Utrecht; Prof. von Kries, who had been offered the chair of physiology in Berlin in succession to Dr. du Bois Reymond, has decided to remain in Freiburg; Dr. Ernst Gaupp to be associate professor of embryology at Freiburg; Dr. Wernicke to be associate professor of hygiene at Marburg; Dr. Karl Bohlin, of Upsala, to be director of the Stockholm Observatory; Dr. James Clark to be professor of agriculture at the Yorkshire College, Leeds, in succession to Prof. James Muir; Dr. Karl Fütterer to be associate professor of mineralogy and geology in the Polytechnic Institute at Karlsruhe; Mr. Louis M. Dennis to be professor of analytical chemistry in Cornell University; Mr. Henry S. Jacoby to be professor of civil engineering; Mr John Henry Barr to be professor of machine design; and Mr. Joseph E. Trevor to be professor of physical chemistry in the same University (Cornell); Dr. Karl Kaiser to be associate professor of physiology in the University of Heidelberg.

THE *Journal* of the Society of Arts gives the following particulars with reference to the fourth meeting of the Congrès International de l'Enseignement Technique, to be held this year in London. The previous meetings of the Congress were—in 1886 at Bordeaux, in 1889 at Paris, and in 1895 at Bordeaux. The meeting will be held at the invitation of the Society of Arts, and of the Worshipful Companies of Drapers, Fishmongers, Goldsmiths, Merchant Taylors, and Clothworkers. The Congress will be opened at 11 o'clock, on June 15, by an address from the President, the Duke of Devonshire, K.G., and from the President of the last Congress, M. le President Léo Saignat. The meetings will be held on Tuesday, Wednesday, Thursday, and Friday. The subjects for discussion at the Congress will include:—Technical Education: (1) Advanced Instruction. Polytechnics, Universities, Colleges. (2) Secondary Instruction. Higher Technical Schools; Secondary and Intermediate Schools; Evening Schools. Commercial Education: (1) Advanced Instruction. Colleges; High Schools and Institute of Commerce. (2) Secondary Instruction. Commercial Schools; High Schools; Classes for Adults. It is not proposed to deal with elementary technical or commercial education. The education of both sexes will be included. The proceedings of the Congress will be reported in English. Papers intended for the Congress may be in French, German, or English, and speakers may make use of any of these languages. All communications relating to the business of the Congress should be addressed to the Secretary, Society of Arts, John Street, Adelphi, London, W.C.

CHILDREN are always interested in natural history, and with a little help and encouragement they become keen collectors and quick observers. Prof. W. A. Herdman relates, in the tenth annual report of the Liverpool Marine Biology Committee, how the aquarium at Port Erin is used as an educational influence. "For example," he says, "if a boy brings us a light-coloured shanny, caught in a shallow exposed pool, we can place the little fish in a deep vessel in semi-darkness under a table, or cover it with some brown sea-weed, the result being that when the boy comes next day to look for his specimen, he has been known to exclaim, 'Hullo! where is my shanny?' There is only a black one here.' It is then easy, by putting the fish into a shallow white dish in the bright sunlight, in a short time to turn the black shanny into what he recognises as the light-coloured one he caught. You can then tell him of the beautiful pigment cells of the skin, and show them to him under a microscope in a small living fish, in a watch-glass full of sea-water. You can show him a speckled shrimp hiding in sand and a mottled shrimp in gravel, and the little prawn *Virbius*, which may be almost any colour according as you change its surroundings from green to red or to dark brown sea-weeds. You explain the difference in pigmentation on the upper and lower sides of a flat fish, you remind him of the chamæleon, tell of Lord Lister's observations on the change of colour in the skin of the frog, and—most beautiful experiment of all—show him the 'blushing' of the newly-born cuttle-fish. From this there opens up a wide range of physiology, of the influence of light and the controlling action of nerves, not to mention natural selection and evolution in general. This is only one of many examples that might be taken. Almost any of the common marine animals, if carefully watched as to structure and habits, show us interesting cases of adaptation to their surroundings and mode of life."

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 4.—"Second Report on a Series of Specimens of the Deposits of the Nile Delta, obtained by Boring Operations undertaken by the Royal Society." By John W. Judd, C.B., LL.D., F.R.S., Professor of Geology in the Royal College of Science. Communicated by desire of the Delta Committee. Received February 11.

The last report on the borings undertaken in the Delta of the Nile under the auspices of the Royal Society was communicated to the Society by the direction of the Delta Committee on November 12, 1885, and published in No. 240 of the *Proceedings*. This report dealt with the materials obtained from the three borings made at Kasr-el-Nil, at Kafr-ez-Zayat, and at Tantah, which reached depths of 45 feet, 84 feet, and 73 feet respectively. Although these borings made known to us the character of the delta deposits at greater depths than the explorations made by Mr. Leonard Horner and M. Linant de Bellefonds, yet none of them succeeded in reaching the solid rock on which these deposits lie, and in which the Nile Valley was originally excavated. It was therefore decided by the Delta Committee to make still more strenuous efforts to attain this result.

In their attempts to carry out this important work, the Delta Committee have received the most valuable aid from the Secretary of State for War, the Inspector-General of Fortifications, and the officers of the detachment of the Royal Engineers attached to the Army of Occupation in Egypt.

Zagazig having been chosen as a suitable site for the next attempt to penetrate the delta deposits, a boring with a 5-inch tube was carried down to 97 feet, with a 4-inch tube to 190 feet 6 inches, and with a 3-inch tube to 345 feet.

From the surface to a depth of 115 feet the strata passed through in the Zagazig boring closely resembled those already reported upon as occurring in the three earlier borings of Kasr-el-Nil, Kafr-ez-Zayat, and Tantah, and consisted of alternations of desert-sand and Nile-mud.

At the depth of 115 feet a very noteworthy change was found to occur in the characters of the beds passed through, a mass of coarse sand and shingle being met with, and this continued to the depth of 151 feet. At the latter depth a band of yellow clay 2 feet thick was passed through, and under it sand and shingle beds prevailed till the lowest depth reached, 345 feet. In some of these shingle beds the fragments, which were usually well rounded—often, indeed, perfect pebbles—were very coarse, the fragments being of all sizes up to that of a hen's egg.

It is interesting to note that a boring made at Rosetta in the summer of 1885 by Mr. T. E. Cornish, C.M.G., Director of the Alexandria Waterworks, gave a section very similar to that at Zagazig. This boring was carried down by a 5-inch tube. Various beds of sand and mud, the latter containing in some places impure lignite, occurred down to the depth of 143 feet 8 inches from the surface, but at this latter depth a mass of "coarse sand and pebbles" was found, which was followed down for about 10 feet.

It will thus be seen that in the case of the Zagazig boring we find at the depth of 115 feet 8 inches (89 feet below sea level) a sudden change from the blown sand and alluvial mud of the Nile delta to masses of shingle and sand, and that the same change is found to take place at the Rosetta boring at a depth of 143 feet 8 inches (134 feet 4 inches below sea level). That these shingle beds were deposited under totally different conditions to those which prevailed while the delta deposits were laid down, and that they were in fact the product of ordinary fluviatile action, can scarcely be doubted, and the determination of the geological age of the great gravelly deposit which is now shown to underlie the modern delta deposits, and to attain depths which certainly in places exceed 230 feet, becomes a problem of the greatest importance and interest.

That the surface of these old gravelly deposits is a very uneven one is indicated by the difference of depth at which it is found at Rosetta and Zagazig respectively. It is possible, indeed, that this gravelly floor may in places rise through the whole of the Nile deposits, and form the present surface of the country. The late Sir Samuel Baker, in a letter addressed to the Delta Committee on February 20, 1886, called attention to the existence of the so-called "turtle-backs," which he regards as interesting proofs of "the pre-existence of desert, before the Nile deposit had converted the lower level into delta."

In spite of the most careful search, not a single organism has been found which lived when the shingle beds were deposited, and which would serve to throw light on the geological period to which they must be assigned. As, however, it was of considerable interest to determine the source of the various pebbles making up the deposit, which we may conveniently speak of as the "Sub-delta formation," I placed myself in communication with Dr. Karl von Zittel, of Munich, who possesses such a unique knowledge of the rocks and fossils of North-eastern Africa. In his obliging communication, he has indicated the probable source of the pebbles which I forwarded to him, and writes as follows:—

"The quartz and chalcedony pebbles, from depths of 120, 160, 245, and 270 feet, are almost absolutely pure examples of those rocks. The sandstones (for example, those from the depth of 120 feet) rather recall, in their general appearance, the Tertiary Sandstone of Gebel Achmar, near Cairo, than the older (Cretaceous) Nubian Sandstone of Upper Egypt. The quartz and chalcedony pebbles, before referred to, might also be derived from the Gebel Achmar Sandstone. The absence of limestone pebbles is striking; it would appear that only the harder rocks have been preserved in the gravels of the Delta, the softer ones having been possibly worn away."

With respect to the igneous rocks found as pebbles in these shingle beds, Dr. von Zittel suggests, from their macroscopic appearance, that they may be derived "from the side valleys of the Arabian Desert." Of metamorphic rocks, quartzites, which are evidently altered sandstones, were found somewhat frequently. Many pebbles of sandstone, sometimes showing stratification and fault-structures, but destitute of organic remains, were obtained at various depths.

Pebbles of flinty limestone from various depths contain recognisable Foraminifera, and one is crowded with specimens recognised by von Zittel as "belonging to the Textularidæ, Rotalidæ, and Globigerinæ." Of these there are other specimens from a depth of 270 feet. Dr. von Zittel states:—"I hold it as probable that these pebbles come from the Eocene of the Nile valley. Flinty layers and concretions are extremely common in the Egyptian Eocene (as, for example, in Central and Upper Egypt). The absence of sections of *Nummulites* and *Alveolina* is particularly noticeable."

At the depth of 121 feet, a pebble of a somewhat different class of rock was obtained. This rock may have come from a Cretaceous deposit, and not from the Eocene, like the others.

Of the general sources from which these pebbles were derived, Dr. von Zittel writes as follows:—

"On the whole, it appears to me conceivable that these gravels under the delta originated at a time when the Nile had already formed its present valley, but not to so great a depth as at present. The majority of the rolled rock-fragments would seem not to have been derived from points extremely distant from those in which they are at present found."

There can scarcely be the smallest doubt that in this Sub-delta formation we have a series of deposits, which were formed under totally different conditions from those which prevail in North-eastern Africa at the present time. The land must have been at an elevation at least from 100 to 300 feet higher than at present; and the Lower Nile, instead of forming an alluvial flat, as at present, must have deposited coarse sands and gravels. It is upon the very uneven surface of this Sub-delta deposit that the alluvial mud and sands of the delta have been deposited, as the surface gradually subsided below the level of the Mediterranean.

The interesting problem of the geological age of this Sub-delta deposit remains to be solved, but it may be hoped that the explorations now being carried on by the Geological Survey of Egypt, under Captain H. G. Lyons, R.E., will furnish new and important evidence bearing on this important question.

It is to be regretted that the borings carried out by the Royal Society have not set at rest the doubts which have long existed as to the depth at which the solid rock-floor lies below the surface of the delta. But while this has not yet been accomplished, it is satisfactory to have been able to show that the supposed insignificant thickness of the alluvial deposits is altogether a mistake; while the existence of an underlying formation, laid down under conditions totally different to those which prevail at present, has been demonstrated.

Communications have lately passed between the English War Department, the Egyptian Public Works Department, and the Royal Society, which lead us to hope that borings, to be shortly undertaken for economic purposes, may, either with or without aid from this Society, supply the means of reaching greater depths than that obtained at Zagazig, and possibly of reaching the old floor of solid rocks on which the Sub-delta deposits rest.

Geological Society, March 24.—Dr. Henry Hicks, F.R.S., President, in the chair.—The following communications were read:—Notes on some volcanic and other rocks which occur near the Baluchistan-Afghan Frontier, between Chaman and Persia, by Lieut.-General C. A. McMahon and Captain A. H. McMahon. In the first part of this paper Captain McMahon

described briefly the physical geography of th Baluchistan deserts, which extend along the south of the Helmund River, between Quetta and Persia. Taking first the plains and their drainage-system, he showed how the wide alluvial plains of Shorawak and Chagai were probably in earlier times one large lake. North and west of these plains, as far as Persia, lie vast deserts of sand, which in places were gradually encroaching upon and burying the mountain-ranges which rise up like islands in the desert. He showed how the sand had intercepted all the drainage from the mountains and prevented it from making its way, as it would otherwise have done, into the Helmund River and the God-i-Zirreh Lake. Turning next to the mountains, Captain McMahon described a well-defined line of fault, which he traced for a distance of about 120 miles from north of Chaman, along the Khwaja Amran and Sarlat mountain-ranges to Nushki. East of this fault all the rocks appeared to be sedimentary; while those to the west were all, with few exceptions, volcanic and igneous. The mountain-ranges in the desert described appeared to be all volcanic, and reference was made to the Koh-i-Taftan, 12,600 feet high, lying south-west of them, which is still an active volcano. The curious, grotesquely-shaped peaks of the Koh-i-Sultan range were then briefly described, and especially that named Neza-i-Sultan—a gigantic natural pillar of volcanic agglomerate many hundreds of feet high. After thus describing the general character of the country, Captain McMahon pointed out the very remarkable force and activity with which certain natural agents were at present at work there—namely, water, wind, sand, and extremes of heat and cold. In the second part of the paper General McMahon described the microscopical characters of the rocks, which consist of lavas, ashes, pumice, igneous intrusive, and sedimentary rocks. In the discussion which followed, the President remarked, concerning the corrosion of basic minerals by silica, that silica might be truly a corrosive mineral, but hitherto the idea had been that the basic mineral had decomposed *in situ*, and that the silica had filled up the hollows and cracks resulting from this decomposition. Mr. Griesbach considered the paper a valuable contribution to our knowledge of Baluchistan. But, having spent some years in that part of Asia himself, he wished to point out that there is abundant evidence to show that the Pliocene deposits which are seen in Shorawak and the neighbouring Registan have not been laid down in a lake-basin, but are chiefly of a fluviatile nature. Dr. Blanford referred to the great prevalence of Tertiary and Cretaceous rocks throughout the wide area extending from the Indus to Mesopotamia. The volcanic rocks of Eastern Baluchistan, like the Deccan traps of India, appear to be of Cretaceous and Lower Eocene age; but the igneous formations near the Baluchistan and Persian frontier must be, in part at all events, of far more recent origin, some of the cones of loose materials seen by the speaker between Bampur and Bam, having undergone no change through denudation. The Rev. Edwin Hill said the pinnacle shown resembled a magnified earth pillar. Was the water which disappeared in the sand ultimately evaporated? Prof. Milne made special reference to the fault which Captain McMahon had described, and compared it with a fault which in 1891 had been formed in Japan. Mr. Cadell said that the remarkable peaks described by the author, which were said to be of agglomerate, might be explained on the supposition that these were the necks of old volcanoes, the upper parts of which, together with the surrounding strata, had been denuded away. Prof. Judd called attention to the great steep-sided masses of volcanic agglomerate which rise up in the midst of the town of Le Puy in Central France, and are crowned by the cathedral and the church of St. Michel. These seem comparable, though of smaller dimensions, to the great columnar masses described by Captain McMahon. There is no doubt that the masses of Le Puy are relics left by denudation of a mass of volcanic agglomerate that once filled the whole valley. The reason why these masses have escaped removal by denudation is probably not because they are "volcanic rocks," but because these materials have been consolidated by the action of siliceous, calcareous, or chalybeate springs. Dr. H. Woodward and Mr. W. W. Watts also spoke, and the authors replied.—On the association of *Sigillaria* and *Glossopteris* in South Africa, by A. C. Seward. In this paper the author described in detail several specimens of fossil plants submitted to him by Mr. David Draper, of Johannesburg. His conclusions as to the geological age of the plant-bearing beds differed from those arrived at by Mr. Draper from stratigraphical evidence; the plants pointed to an horizon which may be referred to what is now termed the Permo-Carboniferous age. The difficulty of distinguishing between various forms of *Glossopteris*-leaves was discussed at some length; and the opinion expressed that it is practically impossible to separate the Indian, Australian, and African forms of *G. Browniana*, *G. indica*, and others. The chief interest as regards the plants centred round the specimens of *Sigillaria*; these were fairly well preserved impressions, and were referred to the well-known species, *S. Brardi*. In addition to various forms of the genus *Glossopteris* and the specimens of *Sigillaria*, the following plants were recorded:—*Noeggerathiopsis Hislopi*, *Gangamopteris cyclopteroides*, *Phyllotheca*, *Conites* sp., *Cardiocarpus* sp., and *Sphenopteris* sp.—Notes on the occurrence of *Sigillaria*, *Glossopteris*, and other plant-remains in the Triassic rocks of South Africa, by David Draper. The author gave a brief description of the geology of four localities, within a comparatively short distance from Johannesburg, from which several fossil plants have recently been obtained. He considered the plant-bearing beds to belong to the Lower Stormberg Series of Dunn, and to the horizon known as the Molteno Beds. The most important locality described in these notes was that of Vereeniging, thirty miles south of Johannesburg, where the author found several specimens of *Sigillaria* associated with *Glossopteris* and other plants in iron-stained sandstones. The significance of this discovery of *Sigillaria* was briefly discussed. —In the discussion on the two preceding papers, Dr. Blanford said that it was a source of much gratification to those who, despite the views of many European palæontologists, had maintained for years on geological evidence that the *Glossopteris*-fauna was Palæozoic, to find their contention confirmed by recent botanical discoveries. Mr. Griesbach pointed out that the fossil plants exhibited, showing true Carboniferous types associated with *Glossopteris*, constituted another and valuable contribution to our knowledge of these beds, which were known as Gondwanas in India; and they confirmed in a striking manner the fact, already accepted in India and Australia, that the lowest beds of this group of strata belonged to the later Carboniferous and Permian systems. Prof. Seeley stated that when he visited Aliwal North in 1889, Mr. Alfred Brown showed him many plants which he had obtained in white sandstone. They included *Glossopteris* and Lepidodendroid plants, together with a variety of ferns, which might be new. There was no opportunity of visiting the locality; but Aliwal North was near the top of the Karoo Series, and he though that Mr. Brown's plants might be from beds yielding *Euskelesaurus*, which he would place above the Indwe coal. There were indications of coal near the base of the Karoo and in the middle, but the workable beds which he had seen were towards the top; although their flora was not the same as in the beds worked by Mr. Brown, which resembled the types now exhibited. He should like to see better evidence of the age of the beds before admitting them as Permo-Carboniferous, because the whole of the South African vertebrata of the Karoo appeared to be below the beds which are found near Aliwal North. The Lower Karoo comprised the zone of *Pareiasaurus*. Then came the zone of *Dicynodon*. Above that is the zone of *Ptychognathus*. And at the top is the zone of the Theriodont reptiles, which he placed below the Cape coal. He had regarded all these beds as Permian. Mr. Stonier observed that in New South Wales *Glossopteris* was characteristic of the more important of the productive Coal-Measures. Feistmantel had described the Palæozoic plants; but there was a difficulty, as stated by Mr. Seward, in distinguishing forms; and in 1894 Mr. R. Etheridge, jun., pointed out that the whole question of generic name, specific characters, &c., of *Glossopteris* had become almost hopelessly involved. *Gangamopteris* and *Glossopteris* were associated at Lochinvar and Newcastle (N.S.W.).

EDINBURGH.

Royal Society, March 15.—Lord Kelvin in the chair.—Dr. James Kerr Love, Glasgow, read a paper on deaf mutism and its prevention. He divided deaf mutism into two classes—the one caused by disease, the other due to heredity or congenital causes. Dealing with congenital deafness, a tree was shown of a family, called the Ayrshire family, where about forty deaf mutes resulted during five generations. Dr. Love's conclusions with regard to the transmission of deafness were that congenital deafness was hereditary either in the direct line, or it might be the expression of a tendency which was seen only in the collateral branches of a family. The anatomical lesions upon which deafness depended, were not one but many. The intermarriage of the deaf, therefore, only perpetuated without

accentuating the tendency. In Great Britain, the tendency to have deaf progeny was about the same, whether one or both parents were congenitally deaf. Adventitious or acquired deafness ending in mutism, was not usually hereditary. The hearing brothers and sisters of a congenitally deaf mute, were as liable when they married to have deaf progeny as the deaf themselves. Consanguinity of the parents emphasised family defects in the children, and in this way many cases of congenital deafness arose. Dr. Love asserted the right of the State to control the marriage of those who belonged to badly tainted families, and were likely to transmit deafness.—Mr. W. R. Laing communicated a note on an analysis of human gastric juice, which he had procured from a fistulous opening of the stomach. His analysis proved the presence of free hydrochloric acids.—Dr. John Murray gave the first of two papers on the structure and origin of coral reefs. He recapitulated his old theory as opposed to Darwin's, and showed that evidence since procured supported his view. A still greater number of submerged volcanic cones, which were the foundations of coral atolls, had been discovered in the coral seas. Some were rising by the accumulation of shells and various dead calcareous animals. Others were being worn down by tidal action in the same way as certain parts of the ocean bed is kept clear of mud. These facts helped his theory. The second paper will deal with the growth of the corals, and more especially with their food.—Mr. J. Erskine Murray laid before the Society a new form of constant volume air thermometer, which shows the total pressure directly, and may be graduated in degrees of temperature. The feature of the instrument is an arrangement whereby the pressure of the atmosphere is eliminated by the adjustment of an auxiliary reservoir of mercury. The total pressure of the air, and hence its temperature, is measured directly by the height of a column of mercury. To the bent stem of the air bulb a barometer tube with a vacuum at the top is connected, and the stem is continued in flexible form to the mercury reservoir. The barometer tube is graduated in absolute degrees of temperature by fixing one point—the pressure for the temperature of melting ice—and dividing the tube mechanically. To make an observation of temperature the mercury is adjusted to a mark fixed on the bulb-stem, by raising or lowering the mercury reservoir, and the pressure of the enclosed air is given by the height of the mercury in the barometer tube over the mark in the stem of the air bulb. By closing a stop-cock between the pressure gauge and the reservoir, the bulb and the gauge may be completely cut off from external pressure.

PARIS.

Academy of Sciences, March 29.—M. A. Chatin in the chair.—Second note on asynchronous motors, by M. A. Potier.—On the transformations of the sugars and on levulic acid, by MM. Berthelot and André. A thermochemical study of the various modes in which glucose is decomposed by yeast, alkalies, and acids. All three reactions are exothermic, and evolve approximately equal amounts of heat.—On the fatty materials found in the Egyptian tombs at Abydos, by M. C. Friedel. The presence of partially hydrolysed glycerides of palmitic and stearic acids was proved, showing that the original grease probably consisted of beef or mutton fat.—On the transformation of the diamond into graphite in the Crookes' tube, by M. Henri Moissan. By the molecular bombardment in a high vacuum, Crookes showed in 1879 that the face of the diamond became covered with a blackish deposit. By its behaviour towards oxidising agents this deposit is now shown to consist of graphite, proving that the diamond must attain on its surface a temperature approaching that of the electric arc.—On the Inseminea without ovules, forming the subdivision of the Inovulæ or Loranthineæ, by M. Ph. van Tieghem. A further note on the classification of the Inseminea.—On the transformation of algebraic equations, by M. Brioschi.—Remarks by M. Henri Moissan on the presentation of his work on the electric furnace.—The Academy nominated the Committees to act as judges for the prizes awarded in 1897, bearing the names of Jecker, La Caze (Chemistry), Delesse, Desmazières, Montagne, Thore, Savigny, Gama-Machado, Montyon, and Bréant.—Emission of liquid water by vegetables: new method for this study, by M. Maxime Cornu. The method described is based upon the use of an electrical counter for automatically recording the number of drops of water exuded from a given surface.—On associated congruences, by M. C. Guichard.—On the singularities of partial differential equations, by M. Jules Beudon.—On interpolation, by M. Émile Borel.—On the successive differentials of a function of several independent variables, by M. E. Goursat.—On a complete apparatus for researches relating to electro-magnetic waves, by M. Jagadis Chunder Bose. The apparatus described, although occupying but a relatively small space, suffices to show the reflexion, refraction, diffraction, double refraction, rectilinear, circular, and magnetic polarisation of electro-magnetic waves.—Mutual actions of the electrodes and kathode rays in rarefied gases, by M. H. Deslandres.—On the propagation of strains in metals submitted to stresses, by M. Mengin. A description of experiments performed on aluminium, nickel-steel, Delta metal, and brass.—On the chlorobromides of tin, by M. A. Besson. These substances are formed by the action of hydrogen bromide upon stannic chloride, and by the action of bromine upon anhydrous stannous chloride in carbon tetrachloride solution, the latter method giving the best yield. The chlorobromides were separated by fractional distillation under reduced pressure, $SnCl_3Br$, $SnCl_2Br_2$, and $SnClBr_3$ being isolated.—On the conditions under which sulphur and hydrogen directly combine, by M. H. Pélabon. Hydrogen and sulphur combine slowly to form sulphuretted hydrogen at temperatures between 215° and 350°, and the reaction is a limited one, although hydrogen sulphide is not decomposed under 350°.—Action of bromine and hydrobromic acid upon ethyl acetate, by M. Boleslas Epstein. The results obtained in this experiment differ in some respects from those previously published by M. Crafts, the products being ethyl bromide, monobromacetic acid, and hydrobromic acid; the latter in considerable quantity. Experiments with ethyl monobromopropionate gave analogous results.—On the formation of native iron carbonate, by M. L. De Launay. The view is put forward that agglomerated iron carbonate has not been, as is generally held, deposited as carbonate from water, but that, like calamine and cerussite, it has been produced by the action of limestone upon the salts arising from the destruction of iron sulphides. It is pointed out, in confirmation of this view, that whilst massive sulphide of iron is always found in schists, the carbonate occurs with limestone.—Clasmatosis in the Lamellibranchs, by M. Joannes Chatin.—On the organisation and relationships of the *Pleurotomaria*, by MM. E. L. Bouvier and H. Fischer.—The refractory period and synchronisation of nervous oscillations, by MM. André Broca and Charles Richet.—Demonstration of the existence of vaso-sensitive nerve regulators of the arterial pressure, by M. C. Delezenne.—Action of the bile and the biliary salts upon the nervous system, by M. Adolph Bickel. The application of bile or of a solution of the biliary salts to the brain of certain animals (cat, dog, rabbit, rat, and guinea-pig) causes cerebral phenomena which vary with the animal, but generally characterised by convulsions and loss of consciousness, accompanied by salivation.—*Pseudocommis Vitis* (Debray) in the tubercles of the potato, by M. E. Roze.—Observations on some properties of the oxydase of wines, by M. Bouffard. Sulphurous acid acts directly upon the oxydase, and completely destroys its oxidising properties. Its use as a preventive of the decolorisation of wines (*la casse*) is specific.—On rye, by M. Balland. The results of proximate analyses are given.—Radiography of a man and a woman, by M. F. Garrigou.—Note relating to an experiment of cone set in rotation on water, by M. Aug. Coret.—Note on electric tourniquets, by M. Galamand.

AMSTERDAM.

Royal Academy of Sciences, February 27.—Prof. van de Sande Bakhuyzen in the chair.—Prof. Franchimont on the nitro group of the nitramines. According to the author, both the acid and the neutral nitramines contain the same group. When in the acid nitramines the hydrogen atom is replaced by metals, the metal may, under certain circumstances, pass from the nitrogen to the oxygen.—Mr. Hamburger, on the influence of carbonic acid upon the volume of the red and the white blood corpuscles. Continuing his investigations (*vide Proc.* November meeting, 1896), Mr. Hamburger observed that not only CO_2, but also other acids, as HCl and H_2SO_4, when added to blood in very small quantities (0·04 per cent.), caused a swelling of those cells, and that an equally small amount of KOH brought about a shrinking. An explanation of these phenomena was given by the author.—Mr. Verbeek gave a survey of the sedimentary formations and the eruptive rocks occurring in Java. The author also made some communications concerning the useful minerals of Java, viz. ores, coal, and petroleum; the last-mentioned substance seems to be present in large quantities in the neo-tertiary strata, not only of Java, but also of Sumatra and Borneo.—Prof. van der Waals, on special points in the melting-

curve. The author demonstrated (1) that the real melting temperature, *i.e.* that temperature at which solid and liquid have the same composition, is the highest temperature at which the solid can ever occur under that pressure; (2) that at that temperature a break in the melting-curve can occur only when the liquid contains no other molecules than complex ones of the composition of the solid.—Prof. Franchimont presented a paper by Dr. van Romburgh, of Buitenzorg, on the action of fuming sulphuric acid upon methylethylaniline and of chromic anhydride upon 2·4 dinitromethylethylaniline.—Prof. Kamerlingh Onnes presented, on behalf of Dr. W. van Bemmelen, of Utrecht, a paper entitled "Values of the terrestrial magnetic declination for the period of 1500–1700, and its secular variation during the period 1500–1850."—Mr. Jan de Vries presented, on behalf of Dr. G. de Vries, of Haarlem, a paper entitled "The motion equations of cyclones." After a discussion of the motion equations in cylinder coordinates, the hypotheses are made that the radian and the tangential velocities are independent of the height above the ground, and that the motion near the centre is symmetrical with respect to the axis of the clycone.—Prof. Haga presented, on behalf of Mr. D. G. Tiddens, of Gröningen, a paper entitled "Observations on Fomm's experiments on the wave-length of the X-rays." On repeating Fomm's experiments (*Wied. Ann.*, 1896) on the wave-length of the X-rays, it appeared that the maxima which the X-rays produce upon a photographic plate after passing through two narrow slits, do not obey the laws of diffraction; for each edge of the slit produces one maximum, while it depends upon the width of the slit, whether the two maxima coincide or even overlap each other, whereby, *e.g.* the left maximum is caused by the edge of the right slit. Consequently no conclusion can be drawn from these experiments as regards the wave-length.

DIARY OF SOCIETIES.

THURSDAY, APRIL 8.

ROYAL SOCIETY, at 4.30.—The Production of X-rays of different Penetrative Values: A. A. C. Swinton.—Photographic Spectra of Stars to the 3½ Magnitude: F. McClean, F.R.S.—Condensation of Water Vapour in the presence of Dust-free Air and other Gases: C. T. R. Wilson.—(1) Double (Antidrome) Conduction in the Central Nervous System; (2) Further Note on the Sensory Nerves of Muscles: Prof. Sherrington, F.R.S.—On the Breaking-up of Fat in the Alimentary Canal under Normal Circumstances and in the Absence of the Pancreas: Prof. V. Harley.—On the Application of Harmonic Analysis to the Dynamical Theory of the Tides, Part I.: S. S. Hough.—On Boomerangs: G. T. Walker.—Kathode and Lenard Rays: J. A. McClelland.

SUBMARINE CABLE LAYING AND REPAIRING.

Submarine Cable Laying and Repairing. By H. D. Wilkinson, M.I.E.E. Pp. 401. (London: *The Electrician* Printing and Publishing Company, Ltd., 1896.)

THIS is not a scientific treatise on the electrical principles involved in submarine telegraphy; it covers, however, rather more ground than is set forth in the title, being also some sort of text-book for the electrician engaged in cable work. Mr. Wilkinson has treated his subject entirely from an up-to-date point of view, without attempting to show what has led to the present state of affairs, which, by the way, are the same—fundamentally speaking—as they were some thirty years ago. The method of working cables by machine transmission is not dealt with here; neither must the reader expect to find any matter relating to the duplex system of Messrs. Muirhead and Taylor, or that of others.

That portion which bears on construction might be more ample with advantage, especially as there are many engaged in submarine telegraphy who have never seen a cable made from start to finish. This remark particularly applies to the preparation and construction of the component parts of the insulated core, whether of gutta-percha (by Willoughby Smith's process or otherwise) or of vulcanised india-rubber, as well as of their collection in the state of nature. Much useful instruction is afforded with regard to the copper composing the conducting wire in a paper on electrical conductors, read by Mr. W. H. Preece, F.R.S., before the Institution of Civil Engineers in 1883.[1] Mr. Wilkinson has well, though briefly, described the constitution and application of the jute serving applied to the core of the iron sheathing, and of the outer covering, besides that of Bright and Clark's compound. The author has nothing to say on the subject of hempen cables, as suggested by Bullivant and afterwards by Trott and Hamilton. This silence is, however, justified by the fact that though a trial has been given to the latter in mid-Atlantic, the experiment has not culminated in further use. A cable without any iron armour appears, on the face of it, to be admirably adapted to recovery from great depths. The best quality of hemp decays, however, in salt water, even when by itself, to an extent sufficient to make the picking up of such a cable an almost impossible feat—not to mention the difficulties in the way of laying it down at a suitable angle.

No doubt Fig. 27 is intended to represent the ordinary close-sheathed type of the present day, but it rather suggests one of the alternate iron and hemp (low specific gravity) combinations, such as were once in vogue with a view to easy laying and recovery, but which, it is satisfactory to know, has long since been abandoned owing to its lack of durability.

Mr. Wilkinson gives us a strong chapter or two regarding submarine survey and sounding work, with good descriptions of the apparatus employed. At the present time, however, the line is supplied in lengths of as much as 7000 fathoms, thus rendering splices quite unnecessary in all depths so far dealt with. Nowadays, we also find that, provided a sinker is selected with sufficient weight for the depth, it will descend at a rate which will ensure the striking of bottom being readily observed. It is, therefore, no longer essential that the drum holding the wire should be particularly light; indeed, it is usually made of a sufficiently substantial character to permit of the wire being coiled direct on to it. Moreover, Lord Kelvin's plan of balancing the weight of wire outboard by weights added to the brake, has long since been abolished. The only proper method of preserving specimens of the bottom—partly for after-examination under a microscope—is to force the sample, *immediately* after recovery, direct from the "sounder" into an open glass tube, to be afterwards closed at both ends with corks, and hermetically sealed. The sample, when examined at any time, is then a true record of the bed of the ocean from whence it came. This plan was brought forward some years ago by Lieut. D. Wilson Barker, R.N.R. The water and mercury piezometers of Mr. J. Y. Buchanan come in for notice here. For a future edition, Mr. Wilkinson might find profit from a study of Mr. Buchanan's papers with reference to the various sounding and survey expeditions he has accompanied in H.M.S. *Challenger*, on the west coast of Africa and elsewhere. In this connection, the author and reader may also be recommended to peruse a paper, contributed by Lieut. Anthony Thomson, R.N.R., to the Sixth International Geographical Congress (1895), entitled "Remarks on ocean currents, and practical hints on the method of their observation." The importance of noting the nature, and measuring the strength, of deep-sea currents is better understood now than it used to be. It can, in fact, scarcely be over-estimated. In several instances of cables, past as well as present, much trouble and many repairs might have been saved had these matters been duly considered previous to laying. For further information regarding sounding work in its connection with submarine telegraphy, the reader should apply himself to a paper on the subject by Mr. Edward Stallibrass, in the *Journal* of the Society of Telegraph Engineers, 1887.

The various systems of landing shore ends under different conditions are all well set forth in this book; and, moreover, clearly illustrated.

Paying-out apparatus is gone into at some length. The cardinal principles, as first defined and put into practice, are closely identified with the names of Newall, Bright, Edwin Clark, Canning, Clifford, Appold, Amos, Siemens, Jenkin and Webb. The laws which govern the rate of paying out under given conditions are partially touched on in this treatise, though no reference is made to the heated controversy which arose in 1876 between Messrs. Longridge and Brooks, on the one hand, and the late Dr. Werner Siemens, on the other, as to whether the friction introduced by a body moving in fluid varied as the *square* of the velocity, or merely as the velocity. It is usually considered that the longitudinal

[1] *Mins. Proc.* Inst. C.E., vol. lxxv.

coefficient is a result of something between the two, perhaps rather nearer to Dr. Siemens' theory.

Mr. Wilkinson does not seem to be very clear as regards the waters in which teredoes may be expected. This is a question of temperature rather than of depth. Brass taping was first applied for this purpose to the core of some of the "Eastern Extension" Company's cables in 1879 by the Telegraph Construction Company; but it should be understood that this is only used for those types deposited in waters above a certain temperature. By bringing home picked-up cables, however, and laying them afterwards in another part of the world, the germs of the teredo and other boring nuisances sometimes present themselves in places where they had not previously appeared.

Mr. Wilkinson is evidently of opinion that you should find your cable before you make it, for he starts off with a goodly selection of the implements of war as regards the various forms of grapnels employed. To these he should add that of Mr. Henry Benest. As a cutting and holding grapnel, it has done admirable service.

Let us now turn to the electrician's side of the question. The electrical portion of the book is very complete as regards testing, and especially in methods of fault localisation; but it might be more so with reference to the apparatus. The new universal galvanometer of Mr. H. W. Sullivan, on the suspended coil principle, is well illustrated, but not quite correctly described. In the first place, unlike the Thomson marine galvanometer, there is no ironclad cover. Messrs. Weatherall and Clark's ingenious damping device for the "Marine" instrument is dealt with, showing how sensitiveness may be maintained though a suspension is made dead-beat. The principle and working of Varley slides are beautifully illustrated on p. 267, after the manner shown by Mr. W. A. Price.[1]

Testing keys are dwelt on *ad infinitum*. With regard to the battery employed, surely Leclanché cells of any size, with an internal resistance of as much as 5 ohms, are unusual, if the cells are in good condition. Why does Mr. Wilkinson introduce the legal volt here? Surely in this class of work the old B.A. unit may be adhered to? For testing batteries, the author should remember that it is only Muirhead's method (and the modifications of Kempe and Munro) which are free from the objection of running down the battery during the test in such a way as to vary the E.M.F., and so give false impressions. Mr. Wilkinson describes a test of his own, on p. 223, for simultaneously testing the resistance and electro-motive force of a battery, which certainly looks hopeful.

In speaking of thirty seconds as a time allowance for making a "bridge test" during repairing work, it must be remembered that on anything like a long length of cable (and especially if partially coiled up), it takes a material time for the line to acquire its true potential throughout. This book gives a certain amount of information regarding the physical and electrical effect of temperature and pressure on gutta-percha, besides references to the present writer's contributions on the subject by way of explanation. It should be remembered, however, that, in selecting a type of core, the proportions are almost entirely governed by economical considerations for a given "K R" to effect a certain working speed with a limiting factor of safety from a mechanical standpoint.

With regard to the localisation of faults, Mr. Wilkinson gives us admirable accounts of the more recent methods of Sir Henry Mance, C.I.E., Mr. A. E. Kennelly, and others; besides the fall of potential test, due to Mr. Latimer Clark, with the special modification (for ship to shore work) of Mr. J. Rymer-Jones. The author does not, however, appear to show that in fault-testing a great number of observations should be made, besides various methods adopted for checking purposes; neither does he point out that no values should be used in after-calculations which appear, by comparison with the rest, to be untrustworthy. It is also advisable to discard results from one test which appear valueless by comparison with those obtained from the other methods adopted. No hard and fast rules can be made for fault-testing; much must be left to the individual judgment of the electrician according to prevailing conditions, character of fault, &c. Though a fault may have a low resistance, it is sometimes as variable as a high resistance fault; and, if so, it gives equal trouble to locate. One great point to be aimed at is, of course, to make the observations at the moment when the fault is least variable. With reference to Kennelly's break test, experience seems to show that the distance of the break from the testing station, in no way detracts from the value or efficiency of the test—notwithstanding Mr. Wilkinson's remarks. For other ways, however, it is well if the fault be fairly near. If the resistance up to the fault be great, then the battery power should be made in proportion, according to Ohm's law for a given required current. Mr. Wilkinson's limitation to the voltage employed in this test would, under certain conditions, be liable to materially reduce the value of the test from a point of accuracy. In a future edition the author should describe the reproduction method of taking Kennelly's test. It is in several ways preferable to working with the bridge, especially with a variable fault, as observations are made much quicker. Again, it involves the use of only one (dead-beat) galvanometer, thereby simplifying the carrying out of the test, besides reducing the chances of error. With Sullivan's galvanometer, this method, even on board ship, is found to give excellent results. Elsewhere in the book the author well describes and illustrates Mr. Willoughby Smith's ship and shore test during laying operations, besides the modification of the above, for fault-testing, as devised by Mr. H. A. Taylor.

The author also deals cursorily with land lines, describing the underground and beach systems of the Eastern Telegraph Company (as devised by Messrs. Clark, Forde, and Taylor), besides those of the present writer. Moreover, in this connection the Saunders and Bright Lightning Guards are respectively described.

Finally, so far as it goes, Mr. Wilkinson and the *Electrician* Printing and Publishing Company are to be congratulated on the above book as a treatise containing a vast amount of practical information in comparatively few words, such as are well adapted for study by the submarine telegraph engineer and electrician. The illustrations are admirable and almost entirely

[1] "A Treatise on the Measurement of Electrical Resistance," by W. A. Price. (Clarendon Press, Oxford.)

original. In the writer's opinion, the principal change required, before launching another edition, is a complete alteration of the order of the chapters, backed up, perhaps, by a slight amplification of the index.

CHARLES BRIGHT.

THE HISTORY OF GEOGRAPHY.

The Dawn of Modern Geography. By C. R. Beazley. Pp. xvi + 532. (London: Murray, 1897.)

THE practical value of scientific geography has, during the last few years, become so evident to all classes, that the number of students of this fascinating subject has increased to an almost incredible extent, and the growing popularity of the Royal Geographical Society is a standing proof of the fact. The men who travel for the sake of duty or pleasure hasten to communicate to this body the results of their notes and observations, and their "papers" or books supply us with details, often most minute, of the remote countries and regions which we have for long considered to be inaccessible.

Supplied as we are with abundant information about the present conditions of the habitable globe, it is, perhaps, a little difficult for us to bear in mind how small were the beginnings of modern geography, and how little is known about them.

As the documents which formed the libraries and private property of individuals in Egypt and Western Asia become better known to us, we realise that a great caravan commerce was carried on between the peoples of countries which we have hitherto thought to have been entirely separated by impassable deserts and trackless mountains. But though we may recover the names of places by the score, we know nothing about them, and can only dimly guess at their positions; and we find trade or religion, or both, were the causes which induced men to move to any considerable distance from their native cities. Victorious armies brought home specimens of the animals and plants and trees from the countries whither they had marched, but their annalists tell us nothing of the situations of the scenes of their conquests.

The first to set down in writing in our own times a connected account of ancient geography was the late Sir Henry Bunbury; and now, following in his steps, Mr. Beazley has produced an interesting volume in which he has undertaken to trace the history of exploration and geographical science from the conversion of the Roman Empire to A.D. 900.

After the introduction come four chapters which describe the travels of pilgrims, merchants and missionaries; one chapter is devoted to the pseudo-science of the "Dark Ages," and another to Muslim and Chinese geography. The narrative is fully illustrated by a large series of reproductions of early maps. The revision of the whole of Chapter vi., on "Geographical Theory," together with Mr. Beazley's account of the history and use of mediæval maps for the whole book—although Mr. Beazley omits to state the fact—is due, we understand, to Mr. C. H. Coote, of the Map Department of the British Museum. Mr. Beazley could not have fallen into better hands, for Mr. Coote's experience in this branch of cartography is unrivalled.

Mr. Beazley's general sketch of the subject which he gives in his introduction is excellent; it is carefully done, and what is almost as good, there is an absence of "fine writing" throughout, which befits the work. He has read widely, and his remarks will form a useful guide to the early geographical literature of Europe, both in manuscript and print. When, however, he undertakes to discuss Oriental texts and literature, it at once becomes clear that he is only quoting at second-hand, and we feel that it is not his fault that he does not do full justice to the early Oriental missionaries. Whether there be historical evidence of the fact extant or not, it is quite certain that some of the Apostles and their immediate successors made their way into Armenia, Mesopotamia, Persia and the Far East. Already before the end of the second century of our era Bar-daisân, who was born at Edessa A.D. 134 or 154, became a Christian missionary in Armenia, and he wrote polemical treatises against the polytheism of the heathen. Before the end of the third century Mâr Mattai had founded his famous convent on Jebel Maklûb near Nineveh, and there is proof that several other religious houses existed in the neighbourhood at this period.

From a passage in "Arnobius" (ed. Leyden, 1651, lib. II, p. 50) it is pretty clear that Christians existed in the Seres (China), Persia and India; and if this be so, which there is no good reason to doubt, many missionaries must have travelled over the country between Palestine and China, or at least voyaged to the latter country by sea. Early in the fourth century Mâr Awgîn set out for the East with seventy disciples, and founded a great religious house near Nisibis, and about 363 A.D., with Sapor's consent, he sent out seventy-two missionaries to found monasteries in Shiraz and Huzistan. A century later Christianity had extended along the shores of the Persian Gulf as far as the Island of Bahrên,, and the Gospel had been preached by Nestorian missionaries in the south of the Arabian peninsula.

The monastic history of Thomas of Marga would have supplied a number of important facts bearing on the early travels of monks who went from the East to visit the Scete desert and Palestine, and Assemani's dissertation in "Bibl. Orientalis" would have given Mr. Beazley many more. As to the genuineness of the Singanfu bilingual inscription there is no doubt whatever, and we may remark that the Patriarch Ḥênân-Îshô' II. died in 780, and not in 778, as we are told on p. 217, note 3; the first Nestorian bishop was consecrated in China in the seventh century. All these are, however, matters which Mr. Beazley may put right in a second edition; and we hope that some attempt will be made to alter barbarisms like "Jesu Jabus" (p. 213), "Anan-Yeschouah" (p. 217), and "Massoudy" (p. 458), &c. And why does Mr. Beazley hesitate to identify "Doul-Karnain" with Alexander the Great? Alexander claimed Ammon of Egypt as father, and a well-known title of this god is "provided with two horns," a phrase literally translated by the Arabic "Dhu'l karnên."

We gather from a footnote that Mr. Beazley intends to continue this "History of Modern Geography"; and if this be so, we shall welcome a further contribution to the literature of this important subject by so able a writer. In conclusion, we cannot help remarking that the index is so small as to be almost useless.

THE GLACIERS OF NORTH AMERICA.

Glaciers of North America: a Reading Lesson for Students of Geography and Geology. By Israel C. Russell, Professor of Geology, University of Michigan. Pp. x + 210. (Boston, U.S.A., and London: Ginn and Co., 1897.)

A GOOD summary, in a convenient form, of what has been ascertained about North American glaciers, has been for some time a desideratum. Prof. I. C. Russell has supplied it in a volume of moderate size, well illustrated, and written in a cautious and critical spirit. As he points out in his opening words, North America, in reality, affords more favourable conditions for the study of existing glaciers and the records of ancient ice-sheets than any other continent. It affords excellent examples of the three types into which glaciers may be distinguished—namely, Alpine, Piedmont, and Continental. Of the first, specimens are abundant in the mountain system of the West, from "pocket editions" in the peaks of the High Sierra to the huge Seward glacier in Alaska. The latter region also supplies good instances of the Piedmont type, in which, as the name implies, the ice-streams of mountain valleys become confluent on a lowland; while Greenland is a grand case of the "Continental" ice-sheet. Of each of these types Prof. Russell gives careful and lucid descriptions, in the course of which he notices or discusses the more important phenomena of ice action. We must confine ourselves to mentioning only two or three, which bear more especially on general questions. We observe that he draws a distinction between osars and kames, applying the former term to continuous ridges, often many miles long; the latter to irregular hills with basins between. Both are mainly composed of water-worn materials, and are connected with ice-sheets; both exhibit stratification, more or less oblique and cross-bedded; on the surface of both large angular blocks have often been dropped, but the osar, he thinks, has been formed by streams flowing in sub-glacial channels; the kames, by deposition in cavities beneath the ice or in open channels on its margin. Prof. Russell also gives an excellent account of drumlins, those curious elongated mounds, mainly composed of "till," which are among the ice-age puzzles. Of these he suggests as a "working hypothesis" the following explanation. Débris embedded in an ice-sheet tends to impede its movement. If, then, any portion of the latter, owing to local causes, contains an exceptional amount of adventitious material, it may behave in some respects as a large boulder (which, however, is gradually stretched out), the purer ice flowing past and around it. Then at last it may be stranded near the end of the sheet. The contained ice slowly melts, and leaves behind an elongated mound of "till." The hypothesis explains several facts, but is not without its own difficulties, on which, however, we must not enlarge. It is certainly ingenious, and it deserves careful consideration. He gives an excellent description of the Malaspina Glacier, one of the Piedmont type, in Alaska. In its neighbourhood marine shells are found embedded in a boulder deposit, high above sea-level. Prof. Russell does not think it necessary to employ an ice-sheet to bring these shells inland from the bed of the Pacific, and remarks that they indicate very considerable upheaval in quite late geological times. We commend this part of the volume to those glacialists of Britain who repudiate almost with scorn the possibility of an important submergence at a date so recent as the glacial epoch. Perhaps in future we shall hear less of rampant ice-sheets at Gloppa and Moel Tryfan!

As regards Greenland, a good summary is given of the observations of Peary, Nansen, Chamberlin, and others, as well as some excellent and extremely suggestive remarks about buried masses of ice in Kotzebue Sund. We should not, however, be quite so ready to admit the possibility of the central ice in the former country being almost as thick as its surface is high above the sea. Surely it more probably conceals a country similar to, but on a larger scale than, Scandinavia, in which case the watershed would be towards the middle. There is a very clear summary of the diverse views on glacial physics. Prof. Russell concludes these by an "eclectic hypothesis," in which a tinge of sarcasm, perhaps unconscious, seems perceptible. May not the difficulties of the subject be augmented by defective knowledge and an imperfect terminology? Fluid and solid are necessary distinctions in practice and in mathematics, but we cannot be so sure where the border-line lies, how far it depends on circumstances, or even if it has a real existence. But we must conclude. We may hesitate in accepting Prof. Russell's conclusions on one or two points, but not in heartily thanking him for this clearly-written volume, which ought to find a place on the bookshelves of every student of ice and its work.

T. G. BONNEY.

OUR BOOK SHELF.

Hydraulic Machinery. By R. G. Blaine. Pp. viii + 383. (London: E. and F. N. Spon, Ltd., 1897.)

THE term hydraulic machinery is generally confined to the machinery employed for storing up water under pressure, the arrangements for transmitting this power to a distance, and the various machines worked by means of the water pressure thus provided; and the utilisation of this form of power was mainly initiated by Lord Armstrong, whose portrait is given at the commencement of the book. This application of power has proved very serviceable for the intermittent operations required at docks, such as the working of dock gates, swing bridges, lifts, coal hoists, cranes, and capstans, and for raising passenger lifts, large canal lifts, and hydraulic graving docks. Moreover, hydraulic power has been very advantageously employed for various operations on board ship, namely, loading and discharging, steering, the working of big guns, and the movement of turrets; and it has furnished a very rapid and efficient means of riveting. Accordingly hydraulic machinery, as commonly understood, has a wide range; but the author has treated it merely as an important branch of a still wider subject, relating to the flow and measurement of the discharge of water, and the various machines in which water is an active or a passive agent. Only ten sections, out of the thirty-one into which the book is divided, comprising about 170 pages, are devoted to hydraulic machinery in its limited sense; and the rest of the book deals with the general principles of hydraulics, the hydraulic press, hydraulic jacks, the flow of water from orifices through pipes and in open channels, the methods of measuring discharge including water meters, jets, water wheels, turbines, pumps, and hydraulic rams and brakes. The book is illustrated by 272 clear figures and diagrams in the text, and is provided with a suitable

index. Though the book covers too wide a field to afford a thorough treatment of special subjects, it furnishes a useful, concise introduction for students to the general principles of hydraulics, and the machines relating to water.

The Story of the Chemical Elements. By M. M. Pattison Muir, M.A. Pp. 189. (London: George Newnes, Ltd., 1897.)

This book forms one of a series constituting a "Library of Useful Stories," and the object of the author has been to "put forth in some kind of orderly sequence a few of the chief guiding conceptions of chemistry" as exemplified by familiar things and phenomena. Mr. Muir deals with his subject in a philosophical spirit, but we fear he assumes too much of the same spirit in his readers for the book to prove really attractive to people unacquainted with chemistry. It is difficult to expound the elements of chemistry otherwise than by experiment—impossible, in fact, to do so satisfactorily—and we should imagine that the readers for whom the book is intended are of the kind that require very careful wooing. Nearly one quarter of the book is devoted to carefully marking out the distinction between elements and "not-elements," and between physical and chemical change; and though much pains have been taken to interweave homely and attractive illustrations, we doubt very much whether the desired end will be reached. Distinctions of the kind in question cannot be said to be intrinsically interesting, and we think that the author exaggerates both their importance and the nicety of treatment required for the main purpose of his book. The task attempted by Mr. Muir is, as already remarked, a hard one, and when we recall the opinions which he has so often expressed concerning the right method of teaching chemistry, we cannot suppose the task to have been entirely congenial. A. S.

Physics: an Elementary Text-Book for University Classes. By Dr. C. G. Knott. Pp. vi + 351. (London: Chambers, 1897.)

In taking up such a book as that of Dr. Knott's, one cannot help feeling that the attempt to treat such a subject as physics within the limits of a book of between three and four hundred pages, must be attended with extreme difficulty. When, on further perusal, we notice that this work contains references to such subjects as contours, determination of the mean density of the earth, the theory of the formation of mirages both erect and inverted—to mention only a few of those matters which the elementary text-book usually leaves out of consideration—we are struck with amazement. But though it might be said that Dr. Knott treats "*de omnibus rebus et quibusdam aliis*," he has succeeded beyond expectation in making his book not only readable but attractive. To one who has read the subject in other works, or who has attended a series of lectures, it will prove most useful as a help to revising his knowledge and giving him a general view of the whole science, which every year makes it more difficult to obtain; and we feel certain that many a student of physics will be grateful to Dr. Knott for furnishing him with such a useful compendium.

Le Déterminisme biologique et la Personnalité Consciente. By Félix Le Dantec. Pp. 158. (Paris: Alcan, 1897.)

This volume is a sequel of the author's "Théorie nouvelle de la vie," which was published last year. The most interesting feature of that theory was the doctrine that constructive activity of living substance was to be regarded as the chief accompaniment of work, while destruction of tissue took place chiefly during rest. In this work consciousness is regarded as an epiphenomenon which in no way interferes with biological determinism. The author assumes the existence of a molecular consciousness which arises from atomic consciousness, and, by a process of fusion, passes into plastidular consciousness, or that of the lowest living organic element. The consciousness of man or of the higher animals is regarded as the sum of the individual consciousness of the neurons of which the nervous system is composed, and is dependent on the arrangement of the neurons. Starting from these assumptions, the author adopts the views of Duval and Ramon y Cayal, and explains such modifications of consciousness as sleep and altered personality by differences in the relations of the neurons to one another.

Report of Observations of Injurious Insects and Common Farm Pests during the year 1896, with Methods of Prevention and Remedy. By Eleanor A. Ormerod, F.E.S., F.R.Met.Soc., &c. Pp. 160. (London: Simpkin, Marshall, Hamilton, Kent, and Co. Ltd., 1897.)

Miss Ormerod's reports are so well known among economic entomologists, that it is almost unnecessary to state that the latest of her valuable volumes (the twentieth) furnishes interesting and serviceable information upon the insect pests prominent in 1896. One of the worst insect attacks of the season was that of various kinds of caterpillars to leafage of forest and fruit trees. In various localities in Kent, Sussex, Surrey, Hampshire, and other counties, in May last, hundreds of trees were stripped of their leaves by caterpillars of the Oak-leaf Roller Moth, the Mottled Umber Moth, and of the Winter Moth. Miss Ormerod describes the life-histories of these pests, and the measures used to prevent the attacks. A very important account is given of the occurrence of "Onion-sickness," arising from the presence in the bulbs, of the Stem Eelworm, known in this country as causing "Tulip-rot" in Oat-plants, and "Stem-sickness" in Clover. Among other insect pests described, with the means of exterminating them, are the Codlin Moth—one of the yearly troubles of the fruit-grower; Beet Carrion Beetle, which has taken to feed on potato leafage; White Cabbage Butterflies, German Cockroach, Common Earwig, Caddis Worms, Pear and Cherry Sawfly, and Surface Caterpillars.

Miss Ormerod pays an affectionate tribute to the memory of her sister, whose death last August deprived her of a constant companion ever ready to assist her in the investigation and illustration of the life-histories of injurious insects.

Grasses of North America. By W. J. Beal. Vol. ii. Pp. 706. (New York: H. Holt and Co., 1896.)

The first volume of Dr. Beal's "Grasses of North America" was published in 1887, and was a work intended more especially for farmers and students, comprising chapters on the physiology, composition, selection, improving, and cultivation of grasses and clovers. The present volume may be regarded as a separate work. It is confined to the Gramineæ, and constitutes a monograph of the North American grasses, native and introduced, with an illustration of each genus. Some idea of the magnitude of the task may be gathered from the fact that the native grasses alone of North America number about 1275 species, included in about 140 genera; while in Europe there are only 47 genera and 570 species. The author brings to his subject a wide practical knowledge, which will make the work of great value to systematic botanists. There is a useful chapter on the geographical distribution of North American grasses, and a copious bibliography is appended.

The Culture of Vegetables for Prizes, Pleasure, and Profit. By E. Kemp Toogood, F.R.H.S. Pp. 127. (Ulverston: William Holmes, 1897).

Cottage gardeners will find in this little volume many useful hints on varieties of alimentary plants, soil-working, rotation, manures, garden pests, and vegetable culture generally. The book is a trustworthy and practical guide, dealing with methods alone, little attention being given to the principles underlying them.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

Organic Selection.

IN certain recent publications,[1] an hypothesis has been presented, which seems in some degree to mediate between the two rival theories of heredity. The point of view taken in these publications is briefly this:—Assuming the operation of natural selection as currently held, and assuming also that individual organisms through adaptation acquire modifications or new characters, then the latter will exercise a directive influence on the former quite independently of any direct inheritance of acquired characters. For organisms which survive through adaptive modification will hand on to the next generation any "coincident variations" (*i.e.* congenital variations in the same direction as adaptive modification) which they may chance to have, and also allow further variations in the same direction. In any given series of generations, the individuals of which survive through their susceptibility to modification, there will be a gradual and cumulative development of coincident variations under the action of natural selection. The adaptive modification acts, in short, as a screen to perpetuate and develop congenital variations and correlated groups of them. Time is thus given to the species to develop by coincident variation characters indistinguishable from those which were due to acquired modification, and the evolution of the race will proceed in the lines marked out by private and individual adaptations. It will appear as if the modifications were directly inherited, whereas in reality they have acted as the fostering nurses of congenital variations.

It follows also that the likelihood of the occurrence of coincident variations will be greatly increased with each succeeding generation, under this "screening" influence of modifications; for the mean of the congenital variations will be shifted in the direction of the adaptive modifications, seeing that under the operation of natural selection upon the preceding generation, variations which are not coincident tend to be eliminated.[2]

Furthermore, it has recently been shown that, independently of physical heredity, there is among the higher animals a process by which there is secured a continuity of social environment, so that those organisms which are born into a social community, such as the animal family, accommodate themselves to the ways and habits of that community. Prof. Lloyd Morgan,[3] following Weismann and Hudson, has employed the term "tradition" for the handing on of that which has been acquired by preceding generations; and I have used the phrase "social heredity" for the accommodation of the individuals of each generation to the social environment, whereby the continuity of tradition is secured.[4]

It appears desirable that some definite scheme of terminology should be suggested to facilitate the discussion of these problems of organic and mental evolution; and I therefore venture to submit the following:—

(1) Variation: to be restricted to "blastogenic" or congenital variation.

(2) Accommodation: functional adaptation of the individual organism to its environment. This term is widely used in this sense by psychologists, and in an analogous sense by physiologists.[5]

(3) Modification (Lloyd Morgan): change of structure or function due to accommodation. To embrace "ontogenic variations" (Osborn), *i.e.* changes arising from all causes during ontogeny.

(4) Coincident Variations (Lloyd Morgan): variations which coincide with, or are similar in direction to, modifications.

(5) Organic Selection (Baldwin): the perpetuation and development of congenital coincident variations in consequence of accommodation.

(6) Orthoplasy (Baldwin): the directive or determining influence of organic selection in evolution.[1]

(7) Orthoplastic Influences (Baldwin): all agencies of accommodation (*e.g.* organic plasticity, imitation, intelligence, &c.), considered as directing the course of evolution through organic selection.

(8) Tradition (Lloyd Morgan): the handing on from generation to generation (independently of physical heredity) of acquired habits.

(9) Social Heredity (Baldwin): the process by which the individuals of each generation acquire the matter of tradition, and grow into the habits and usages of their kind.[2]

Princeton University, March 13. J. MARK BALDWIN.

[1] H. F. Osborn, *Proc.* N.Y. Acad. of Sci., meeting of March 9 and April 13, 1896; also *Science*, November 27, 1896. C. Lloyd Morgan, "Habit and Instinct," October 1896, pp. 307 ff.; also *Science*, November 20, 1896. J. Mark Baldwin, discussion before N.Y. Acad. of Sci. meeting of January 31, reported in full in *Science*, March 20, 1896; also *Amer. Naturalist*, June and July 1896. The following brief statement has been prepared in consultation with both Principal Morgan and Professor Osborn. I may express indebtedness to both of them for certain suggestions which they allow me to use, and which I incorporate verbally in the text. Among them is the suggestion that "Organic Selection" should be the title of this letter. While feeling that this co-operation gives greater weight to the communication, at the same time I am alone responsible for the publication of it as it here stands.

[2] This aspect of the subject has been especially emphasised in my own exposition (*Amer. Naturalist*, June 1896, pp. 447 ff.).

[3] Introduction to "Comp. Psych.," pp. 170, 210; "Habit and Instinct," pp. 183, 342.

[4] "Mental Development in the Child and the Race," 1st ed., January 1895, p. 364; *Science*, August 23, 1895.

[5] Prof. Osborn suggests that "individual adaptation" suffices for this; but that phrase does not mark well the distinction between "accommodation" and "modification." "Adaptation" is used currently in a loose general sense.

[1] Eimer's "orthogenesis" might be adopted, were it possible to free it from association with his hypothesis of "orthogenic" or "determinate" variation and use inheritance. The view which I wish to characterise is in some degree a substitute for these hypotheses.

[2] Prof. Lloyd Morgan thinks this term unnecessary. It has the advantage, however, of falling in with the popular use of the phrases "social heritage" and "social inheritance." On the other hand, tradition seems quite inadequate; as generally used, it signifies that which is handed on, the material; while in the case of animals, we have to deal mainly with the processes of acquisition. "Social heredity" also calls attention to the linking of one generation to another. However, I think there is room for both terms. For further justification of the terms "social heredity" and "organic selection," I may refer to *Amer. Naturalist*, July 1896, pp. 552 ff.

Unfelt Earthquakes.

THE Icelandic earthquakes, on several occasions mentioned in NATURE—*e.g.* November 5, 1896—have been recorded also by the horizontal pendulum (system v. Rebeur) of Strassburg. I give the dates in Greenwich M.T.

1896.		h. m. s.			h. m. s.
Aug. 26.	Begin	11 22 9 p.m.	End Aug. 27		0 58 37 a.m.
	Max.	11 22 37 ,,	until		0 13 47 ,,
,, 27.	Begin	10 50 18 a.m.	End		11 50 18 ,,
	Max.	11 1 32 ,,	Succeeded by a series of tremors until		12 39 38 p.m.
,, 31.	Begin	8 17 50 ,,	End		11 38 2 a.m.
	Max.	8 29 56 ,,	,,		9 42 12 ,,
Sept. 5.	Small disturbance at				12 50 0 p.m.
,, 6.	Begin	0 31 34 ,,	,,		0 41 4 a.m.
	Tremors succeeded Sept. 6 and 12.				
,, 12.	Begin	8 17 54 ,,	End		10 41 6 ,,
	Deduct max.	8 39 38 ,,	to		10 34 22 ,,
,, 13.	Begin	5 28 56 ,,	End		6 3 16 ,,

The whole of September was very troubled: small perturbations were observed on the 7th, 8th, 14th, 16th, 19th; greater ones on the 22nd, 24th, 25th The time of the perturbations above agrees very well with the disturbances of the Paris and Edinburgh pendulums.

Prof. Milne (NATURE, February 25), asks for information about some earthquakes observed in February 1897, in the Isle of Wight, in Italy, &c. They disturbed very much the new pendulum of Strassburg, system Ehlert, as described in *Beiträge zur Geophysik*, vol. iii. 209 (Leipzig, Engelmann). The system consists of three horizontal pendulums, smaller than Rebeur's, but much heavier, in one box, each set up 120° from the other, and directed the first from E. towards W., the second from N.W. towards S.E., the third from S.W. towards N.E. The movements are photographically recorded, and very much enlarged.

The disturbance of February 7 was unusually large. It commenced on the first pendulum (E. to W.) at 7h. 49m. 50s. a.m., and ended at 8h. 46m. 19s. a.m.; after-shocks were felt until 9h. 41m. 39s. a.m. The perturbation showed two maximum-periods, each divided into two parts. The second pendulum (N.W. to S.E.) was disturbed from 7h. 45m. 25s. a.m.; maximum, 8h. 2m. 8s. until 8h. 24m. 28s.; end, 8h. 40m. 20s.; after-shocks from 9h. 26m. until 9h. 54m.

The greatest disturbance appeared at the third pendulum (S.W. to N.E.), with oscillations 6 cm. large; the maximum, with two well-defined periods, was from 8h. 23m. 52s. until 9h. 8m. 43s. a.m. Tremors followed until 11h. 30m. a.m.; the preliminary tremors of this pendulum, commencing 7h. 45m. 25s. a.m., showed three well-marked maxima. Other very small tremors preceded, the pendulum being troubled all the preceding night, perhaps by the winds.

On February 11, there was a small disturbance on the second and third pendulum 11h. 39m. 48s.; February 13, a very great one on all three pendulums from 2h. 31m. 54s. until 3h. 8m. a.m., with oscillations up to as much as 2·1 cm., and preceded on pendulum three by a preliminary motion, on February 12, from 11h. 2m. 2s. p.m. until 11h. 34m. 38s. p.m.

A very great perturbation was observed on February 19, on the third pendulum, from 10h. 11m. until 10h. 39m. p.m.; and on February 20, from 0h. 11m. 15s. until 1h. 20m. 10s. a.m. The first pendulum (E. to W.) had a very great motion from 0h. 11m. 16s. until 1h. 49m. a.m., February 20, followed by a long series of tremors. The second pendulum was not in activity.

Dr. Ehlert (Strassburg) has put the box with the three pendulums on a short, stout, isolated sandstone pillar, to avoid the earth-waves being concealed or wholly annihilated by the frictions and elastic motions taking place in a large pillar of masonry; and the pendulums, set up in such a manner, give very accurate records of vibrations, change of level, &c. They can be made extremely sensitive. The whole instrument may be purchased for 51*l.*, with recording apparatus and lamp (Strassburg, I. and A. Bosch); and I should like to recommend it, for the seismic survey of the world, for each station of this international survey. The distinct directions and movements of the three pendulums are showing (1) each motion of the earth-crust coming from whatever an azimuth; (2) the chief direction of the seismic wave; (3) the temporary figure of the wave; (4) their splitting-up in different trains of waves. They are disturbed also by vertical shocks.

G. Gerland.

Strassburg, March 31.

Relationship between the Masses and Distances of the Four Outer Planets.

Let the mean distance of Jupiter be the unit of measurement for the four outer planets. The distances are then as follows.

Jupiter.	Saturn.	Uranus.	Neptune.
1	1·8338	3·6869	5·7765

Now take the following numbers as the masses—

Jupiter.	Saturn.	Uranus.	Neptune.
312	92·513	13·604	15·969

and multiply the masses into the distances. We then obtain

Jupiter.	Saturn.	Uranus.	Neptune.
312	169·65	50·157	92·245
J	S	U	N

Let the last series of numbers be J, S, U, N, respectively. Then

$$U S = N^2 \quad . \quad . \quad . \quad . \quad . \quad (1)$$
$$U J = N S \quad . \quad . \quad . \quad . \quad (2)$$
$$U + N + S = J \quad . \quad . \quad . \quad . \quad . \quad (3)$$

In fact, the numbers are in geometrical progression, having a common ratio R = 1·8391. So that

$$U R = N \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$
$$U R^2 = S \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$
$$U R^3 = J \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

The common ratio 1·8391 is nearly the mean distance of Saturn 1·8338, and is one of the solutions of a biquadratic equation

$$x^4 - 2x^3 + 1 = 0.$$

The Hermitage, Coorla, Bombay, March 19.

X-Ray Photography.

It may interest the readers of Nature, that it is possible to take shadowgraphs (so-called) instantaneously without any special arrangement of induction coil or deviation in the form of Jackson tube.

The apparatus used consists of 10-inch Apps' induction coil, a Jackson focus tube supplied by Messrs. Newton (one of a set of twenty-five I have in my possession), and a set of small secondary batteries, about 30 ampère hour capacity, six cells in the set. The induction coil is of the ordinary type with ordinary commutator.

For the purpose of obtaining these results in such short exposures, a special choice of tube is necessary, working the tube for a considerable period before desired condition is arrived at, and that condition judged by experience, for no ampère measurement will give the information. The tube must be strongly heated by a spirit lamp, and when the desired condition (tube being of course connected with coil) is arrived at, the exposure must take place.

(1) By instantaneously turning current on and off.

(2) By interposing a ½-inch iron plate between tube and object to be shadowed, removing plate for the exposure.

Having carefully timed the exposures, I have been able to repeat the experiment with assured success. For some time past I knew that hands and arms of children could be taken in from twenty to thirty seconds, but have now succeeded in taking children's hands in half a second (showing all bones and cell tissue of bones), and adults' hands, bones of wrist, and even arms, with exposure of only one second, again showing cell tissue of bones.

It is interesting to note that everything connected with the production of these results was made in England.

William Webster.

Art Club, Blackheath, March 30.

A New Scientific Club.

My attention has been drawn to a circular in favour of a new Club, in which my name appears as one having consented to become a member. I know nothing of the Club, nor have I in any way authorised the use of my name.

12 Arundel Gardens, W., April 9. W. Ramsay.

DEEP-SEA FISHES OF THE NORTHERN ATLANTIC.

The examination of the deep-sea fishes which have been collected by means of the dredge or trawl during the last twenty-five years, has now been almost completed; at least the results of this examination, as far as it has gone, are now before us, and form the most interesting and attractive portion of the ichthyological literature of our time. The harvest reaped by the various expeditions, surveys, and private enterprises, which have been fitted out to explore the mysteries of the sea, has far exceeded the most sanguine expectations, and it is satisfactory to find that the six or seven volumes devoted to ichthyology have been placed before the public in a style and with a wealth of illustration worthy of the interest attached to the subject. The first to appear was the volume descriptive of the deep-sea fishes collected during the Norwegian Expedition to the North Atlantic from 1876 to 1878, by R. Collett (Christiania, 1880, 4to, pp. 166, with five double plates); this was followed, in 1887 by the Report on the Deep-sea Fishes collected during the *Challenger* Expedition (1873-76), in which were incorporated the proceeds of the Faeröe Channel Exploration (1880 and 1882) (London, 1887, 4to, pp. lxv. + 335, with 73 plates); the collections made by the French expeditions of the *Travailleur* and *Talisman* (1880-83) were described by L. Vaillant (Paris, 1888, 4to, pp. 406, with 28 plates); in the Indian Ocean, H.M. Indian Marine Survey steamer *Investigator* has added largely to our knowledge of the bathybial fauna from year to year since 1885, the collections being described by A. Alcock in a series of papers which appeared in periodicals, and were supplemented afterwards by "Illustrations," of which three parts, with fifteen plates in quarto, have been issued under the authority of the Director of the Royal Indian Marine in Calcutta, 1892-95; finally, the collections made in the North Pacific by the U.S. Fish

Commission steamer *Albatross* (1890–93) have been reported upon by C. H. Gilbert in the annual reports of that Commission.

The past year has been signalised by the almost simultaneous appearance of three works, by which our knowledge of the deep-sea fishes of the Atlantic north of the equator has been vastly increased, and which we propose to notice more particularly in the present article.

By far the most important of those three publications is "Oceanic Ichthyology,"[1] a work devoted to the discussion of the material that has been brought together since the year 1877, by the naturalists on board of the steamers of the United States Fish Commission and Coast Survey. It is almost superfluous to remind our readers that the merit of having organised the systematic investigation of the North-Western Atlantic, and of having continued it for so many years, is mainly due to the late Prof. Baird, his successor Colonel McDonald, the late Dr. Brown Goode, and Prof. Alex. Agassiz.

In "Oceanic Ichthyology" all the species from the Atlantic are fully described, or at least diagnosed, unless they are long- and well-known forms. Incorporated with them are the Bathybial and Pelagic forms inhabiting other oceanic areas, and hitherto not found in the Atlantic; but the authors treat of them only in a more or less general fashion, the species being usually mentioned by name only. The illustrations—417 in number on 123 plates—are very well drawn, though of no particular artistic merit, many being reduced copies in outline from other works. But the work, as it is, is a most valuable contribution to the literature of oceanic zoology, not merely for the scientific student, who will find in it a mine of information, but for all "who go down to the sea in ships, and occupy their business in great waters." If in its production attention has been paid to economy, the great object has been attained thereby of bringing the work within reach of a number of persons to whom the corresponding parts of the *Challenger* Reports will be inaccessible. As the edition seems to be as large as the publications of the U.S. National Museum usually are, and as the work seems to have been distributed with the same lavish liberality, there will be no vessel in the U.S. navy—we hope no vessel in the navy of any nation—engaged in the exploration of the ocean which has not a copy on board.

The American work covers the same ground as the two Reports of the *Challenger* series, which were respectively devoted to the Deep-sea and Pelagic fishes, and even a part of the *Challenger* Shore-fishes, as quite a number of species living above the 100 fathoms line, for instance certain flat-fishes, have been admitted into the work. The authors combine both those kinds of fishes under one term, viz. *Oceanic fishes*, which are defined as "those deep-sea and pelagic species which dwell in the open ocean far from the shore, either at the surface, at the bottom, beyond a depth of 500 feet, or, if such fishes there be,[2] the intermediate zones." By the term deep-sea fishes are understood only "those which are found at a depth of 1000 feet or more, without reference to the question whether or not they also occur in shallower water. The limit of 500 feet is taken for convenience in the study of the origin of local deep-sea-faunas." *Pelagic* fishes are termed "those which live far from land and at a distance from the bottom, rarely approaching the shore except when driven by wind or current. It is those which are most closely associated with the plankton. . . . Some of them, which occur at considerable depths, we call bathypelagic."

We doubt very much whether any appreciable advantage is to be gained by this modification of our more simple method of classifying the marine fish-fauna. The littoral passes into the pelagic and deep-sea-faunas, the pelagic into the deep-sea so gradually, that any line of division that may be proposed, must appear more or less artificial; and this obstacle to classification is not overcome by increasing the number of zones. I believe no malacologist of the present day maintains the eight zones, proposed by E. Forbes; with the increase of our knowledge his boundary-lines were wiped out, although they seemed fully justified at the time when that great genius generalised from the wealth of his own original observations. In the *Challenger* and other Reports, the 100 fathoms line has been selected as the upper limit for the deep-sea-fauna, because we have the positive knowledge, that at that line some of the abyssal conditions obtain, viz. absence of light, absence of surface-disturbance, absence of plant-life. It is obvious that these conditions must operate upon organisms permanently living under them, although many surface forms descend below that line, without any part of their organisation being affected by their temporary sojourn. One of the principal factors which will have to be taken into consideration in determining zones of distribution will be, as is generally admitted, temperature; and since we have been placed in possession of a great number of data of the temperatures of certain depths in definite localities, perhaps the attempt would not be premature to ascertain the zones for that portion of the bathybial fauna which is known to live at the bottom. As to the so-called mid-water fishes, the study of their distribution cannot be attempted until some means of capture is devised, by which the question of their existence, and of the limits of their vertical range is definitely settled.

As far as fishes are concerned, a distinction between pelagic forms and fishes of the plankton cannot be maintained with any advantage. But whether such a distinction be made or not, it is difficult to understand on what grounds the authors have omitted every mention of the important group of flying fishes (*Exocetus*), whilst the dolphins (*Coryphæna*) and other similar pelagic fishes find a place in their list.

An idea of the great labour expended in the preparation of this work may be gathered from the number of species treated therein. We have not counted the species described or referred to, but the authors state in their introduction that "more than 600 (?) different kinds of fish have been obtained from the depth of 1000 feet and more"; further, in the list of "new species" they enumerate 153 species, chiefly from the Western Atlantic[1]; a number which, taken without critical examination of the species, is but little less than that of the species described as new in the corresponding *Challenger* Reports.

Among the new species are a number of very singular forms. Although many of them represent, according to the view of the authors, types of distinct families, the majority are, at any rate, closely related to previously known genera.

The vertical and horizontal distribution is given under the head of each individual species, very often in great detail, for which the authors deserve our best thanks. But they would have added to the usefulness of their

[1] "Oceanic Ichthyology, a Treatise on the Oceanic and Pelagic fishes of the world, based chiefly on the collections made by the Steamers *Blake*, *Albatross*, and *Fish Hawk* in the North-Western Atlantic," with an Atlas of 417 figures, by George Brown Goode and Tarleton H. Bean. (Washington, 1895.) 4to, pp. xxix. + 553. It forms a special volume of the Bulletin Series of the United States National Museum, and is also issued as vol. xxii. of the Memoirs of the Museum of Comparative Zoology at Harvard College, with the same title, but dated "Cambridge, U.S.A., September 1896." *

[2] Called mid-water fishes, *Challenger* Report, p. 33.

* Questions of priority are sure to arise hereafter, and therefore it is just as well to be certain as to the actual date of publication. In the last letter which we received from one of the authors, the late Dr. Brown Goode, and which is dated August 9, 1896, he says: "I am sending you the *first copy* of our 'Oceanic Ichthyology.'" The copies of the work sent out by the Smithsonian Institution reached England towards the end of the year.

[1] Singularly, *Psychrolutes paradoxus*, described some thirty years ago from the Pacific, is also included in this list of "new species"; on the other hand, others are omitted.

work, if they had collected the information as to the bathymetrical limits of the deep-sea forms in some conspicuous form, as has been done in the *Challenger* or some of the *Blake* Reports. With the absence of such a list or table, we have also to regret that the authors have abstained from giving us an account of the general results of their observations; an account which would have been all the more valuable, as it would have proceeded from competent men who were able to form a sound judgment from their personal intimate acquaintance with the subject. They evidently laboured under great disadvantages: they (as they state) had commenced the work in 1881, revising and rewriting it thrice; it was written at odd hours snatched from administrative duties, always under the pressure of haste; whilst later, serious illness delayed its printing. Under such circumstances it is not to be wondered at, that not a few errors, of commission and omission, have crept in, which the authors would or could have avoided if they had been in a position to apply themselves with care proportionate to the magnitude of their task. Thus even the *Challenger* Report on the pelagic fishes seems to have come to their knowledge at a time when it was too late to fully utilise it, as might have been done, at least, in the Appendix at the end of the work. Under *Lycodes murœna* all reference to the *Challenger* description and figure, and to its abundance in the Færöe Channel is omitted. Of other blunders of a more or less serious nature, we will mention one only, viz. the use of the same figure for two fishes of different families. Fig. 42 is a reduced outline-copy taken from the figure of *Alepocephalus niger* in the *Challenger* Report; the same figure, but with the addition of scales, is reproduced under No. 52, where it does duty for *Bathythrissa dorsalis!*

But this is not the place to enter critically into errors which in due time will be corrected by the specialist; they may be annoying to him, but will little interfere with the usefulness of the book to every one interested in the subject, and will not weaken the impetus which this work cannot fail to give to the prosecution of oceanic ichthyology. We have to deplore the premature death of one of the authors, Dr. Brown Goode; but it is some satisfaction to know that he lived, at least, long enough to see the completion of a work which must have been to him, as it is to us, and as it will be to posterity, the lasting record of his untiring devotion to one of the great tasks of his life, viz. the exploration of the marine fauna of his country. There was no more earnest and unselfish searcher of truth; and we have no doubt that, had he been spared, he would have redeemed his promise to work out the general results of his study of the pelagic and bathybial fish-faunas.

The second publication[1] to which we draw attention, treats of oceanic fishes of the Eastern Atlantic. It is part of a series of volumes published by the Prince of Monaco, and descriptive of the results of the cruises which he undertook in the yacht *Hirondelle* in the years 1885 to 1888. Profiting by the experiences of the British and American expeditions, and personally possessing an intimate knowledge of every technical detail, he adapted his vessels especially for deep-sea work, and fitted them with the most perfect apparatus. In the volume before us the fishes are described which were collected, during the period named, between the Bay of Biscay and the Azores, and between the Azores and Newfoundland; they are ninety-five in number, of which about one-half are bathybial or pelagic. Prof. Collett, to whom the examination and description of these materials were entrusted, has carried out this task with the same care which has rendered his Report on the Fishes of the Norwegian North Atlantic Expedition so valuable a contribution to our knowledge of the distribution of deep-sea fishes, as well as of their distinctive characters and structure. Six new species have been added to the Atlantic fauna in the present report. Some of the deep-sea forms were captured by a method not employed in previous expeditions, viz. by sinking baited traps to a depth of 1000 fathoms, thus securing species which, for some reason or other, were never captured by the trawl of the *Hirondelle*. We cannot conclude this short notice without referring to the great artistic beauty of the illustrations of the work; neither can we refrain from expressing our admiration of the scientific spirit which has led the Prince to devote so much of his leisure and wealth to the advancement of knowledge.

We have included the last of the three publications on deep-sea fishes in the present notice, in order to show that even at a small expenditure of time and money excellent results may be obtained in oceanic exploration. The cruise of the French ship *Caudan* was an undertaking of very modest pretension. Being much in need of deep-sea material for purposes of instruction, R. Koehler, Professor of Zoology at the University of Lyons, organised a short cruise in the Bay of Biscay. The sums required to defray expenses for the necessary apparatus were obtained by donations from scientific institutions of Lyons, Nancy and Toulouse, whilst the Minister of the Marine placed the steamer *Caudan*, of 650-horse power, at the disposal of Prof. Koehler for a fortnight. In this short time (August 1895) M. Koehler, in company with three of his colleagues, employed the trawl thirty times, in depths varying from 60 to 1200 fathoms, and was so successful that the results just published fill a handsome octavo volume of 741 pages and 39 plates. Its title is "Résultats scientifiques de la Campagne du *Caudan* dans le Golfe de Gascoigne. Par R. Koehler." (Paris, 1896.) The species of fishes obtained, thirty-five in number, are described on pages 475 to 526, and some of the more remarkable forms figured on plates 26 and 27. Five of the species are described as new, whilst the discovery, in the Bay of Biscay, of others known to exist in other most remote parts of the ocean, adds further evidence of the remarkable fact of the uniformity of the abyssal fauna all over the globe.

Prof. Koehler's experiences of the effect of formaldehyde in the preservation of deep-sea fishes, are well worthy of the notice of future collectors. It is well known that the tissues of many deep-sea fishes are of extreme softness and fragility; by immersion in spirits sufficiently strong for preservation, these tissues are much contracted, the natural shape of the fish often being distorted. This is entirely avoided by the use of the usual 40 per cent. formaldehyde, mixed with twenty times its volume of water. The specimens, however, have to be transferred into spirits after some days, because the formaldehyde has been observed to entirely destroy black pigment in a very short time. A. G.

[1] Résultats des Campagnes Scientifiques accomplies sur son Yacht par Albert 1er Prince Souverain de Monaco. Fasc. x. Poissons provenant des campagnes du yacht *Hirondelle* (1885–8). Par Robert Collett. Monaco, 1896. 4to, pp. viii + 198. With six double plates.

THE MEMORIAL STATUE OF SIR RICHARD OWEN.

SIR RICHARD OWEN'S whale has been removed from its familiar place in the Natural History Museum, and a fine bronze statue of the great naturalist, by Mr. T. Brock, R.A., now forms the most conspicuous feature on the floor of the central hall of that institution. The first view of the statue, as it is seen from the entrance to the Museum, is not prepossessing. Visitors whose business takes them to either of the departments on the ground-floor, pass by with only an uninteresting view of a skull-cap, a vertically corrugated doctor's robe, and a pair of flaps hanging from the arms, suggestive of the rigid "primaries" of a cherub's wings. The front view of the statue, however, is far more pleasing. Owen

is represented as a teacher: he holds a bone in one hand, while the other is outstretched, as if it had just been pointing to some feature in the specimen; the attitude is easy and natural, so that it does not force itself into notice, and the face at once absorbs attention. The likeness is said to be very successful by some of those who knew Sir Richard Owen most intimately. The lines of the face suggest power and vigour; the deeply-shrunk eyes look intently forward; the whole expression is that of a teacher who is speaking with authority, and expects to carry conviction rather than to win it. At the same time the side view of the face gives a suggestion of that kindliness to which Owen owed so much of his social charm. The selection of the specimen which Owen holds in his hand is happy. It is a *Dinornis* femur, and reminds us that it was after an examination of an odd fragment of this bone that Owen, in 1839, predicted that birds larger than the ostrich would be found to have once lived in New Zealand.

The new statue has one great advantage over that of Darwin, which stands on the staircase at the other end of the hall; for its material is bronze instead of marble. Although marble is perhaps the more useful medium for statues of ideal characters like Donatelli's St. George, bronze appears to give more pleasing representations of individual men.

Mr. Brock is warmly to be congratulated on his successful statue, which will permanently remind the public of the services of the great naturalist, to whose persistent agitation we owe the great Museum, that will ever be the truest monument of his life and influence.

PLAN TO GENERATE ELECTRICITY AT THE NILE CATARACTS.

THE Department of Public Works in Egypt has long been engaged on plans for dams on the Nile to improve the irrigation. Having lately learnt that the vast energy now wasted in the rapids, generally called cataracts, on the Nile might be converted into electric power, and conveyed even to considerable distances, where an economical form of power would tend greatly to the development and wealth of the country, they asked Prof. George Forbes to go to Egypt during the period of high Nile, and to investigate and survey the localities where power might be developed to a point as far south as the Egyptian frontier. Prof. Forbes was asked to report on the capabilities of all the rapids, and prepare plans and estimates for works both in conjunction with, and independent of, the proposed irrigation dams. The Report, which is to be completed by September 1898, will further embody the scheme for transmitting the electric power to places where it is wanted.

The principal demands for power which are immediately apparent are (1) for railways, (2) for pumping in connection with irrigation, and (3) for the large sugar factories which are now established. The existence of this power will doubtless also stimulate other industries.

Prof. Forbes has satisfied himself, by personal inspection, that the works required would not be too expensive, and that the economical distance of transmission reaches the places where there is demand for power. The high and low Nile conditions are very different, but this presents no insurmountable obstacle. At the first cataract the available power is at high Nile 500,000 h.p., at low Nile 35,000 h.p.

The pumping works to be started will reclaim vast areas, and raise additional crops on areas now cultivated.

For 4000 years every improvement in the condition of Egypt has come from the Nile and irrigation. So it will be in the future. But it must also be remembered that the sugar-cane industry has already developed to an important extent of late years. The factories use a great deal of power, and the lands growing cane require irrigation by pumps. Here there is an immense field for using cheap power.

The first cataract is the most important to utilise, but the others must also be taken in hand. As an example, before the Mahdi's time, the province of Dongola had 8000 sakias for pumping water of irrigation, now nearly all gone. These used eight head of cattle each, costing 10*l.* a head. Here is a capital expenditure of 640,000*l.*, which will now be saved by using electric pumps, the cost of which is far less. The construction of the desert railway from Wady Halfa to Abu Hamed would have been robbed of its difficulties as to water and coal if electric instead of steam locomotives had been used.

NOTES

THE first of the two conversaziones held annually at the Royal Society will take place on Wednesday, May 19. This is the conversazione to which gentlemen only are invited.

THE Paris Municipal Council has voted a sum of 5000 francs (200*l.*) towards the cost of installation and maintenance of a laboratory for Röntgen photography at the Trousseau Hospital.

THE Lords Commissioners of the Treasury have authorised an extension of Sir William Flower's term of office as Director of the Natural History Departments of the British Museum for three years from the expiration of his retirement date under the age regulation of the Civil Service.

PROF. W. W. HENDRICKSON, head of the department of mathematics at the Naval Academy at Annapolis, has, says *Science*, been appointed superintendent of the American Ephemeris and Nautical Almanac, in succession to Prof. Simon Newcomb. The retirement of Prof. Newcomb, on reaching the age limit fixed by the naval authorities, has called forth many notices in appreciation of his great contributions to science.

THE sixty-ninth annual meeting of the great German Association of Naturforscher und Aerzte will, it is announced, be held this year at Brunswick, from September 20 to 25. The work will be distributed among thirty-three sections, being an increase of three as compared with previous years. One of the new sections is apportioned to anthropology and ethnology, another to scientific photography, and the third to geodesy and cartography.

LORD LISTER will preside at the anniversary dinner of the Literary Fund on May 5.

THE King of Denmark has conferred upon Dr. Nansen the Gold Medal of Merit with the Royal Crown.

A COMPLETE set of the *Challenger* Reports has been presented to Dr. Nansen in recognition of the eminent services which he has rendered to the cause of scientific exploration in high latitudes by his recent expedition in the *Fram*.

WE regret to have to record the deaths of the following men of science:—Dr. de Marbaix, founder and some time director of the Bacteriological Institute of Boma; Dr. Siuku Sakaki, professor of psychology in the University of Tokio.

WE notice with much regret the announcement of the death of Prof. E. D. Cope, professor of zoology and comparative anatomy in the University of Pennsylvania.

WE note with the highest satisfaction the complimentary remarks which the Colonial Secretary, Mr. Chamberlain, made in the House of Commons on Friday, with reference to the Royal Gardens, Kew. When the vote of 112,291*l.* for Royal

parks and pleasure grounds came before the Committee of Supply, Mr. Burns brought up the question of opening the gardens to the public earlier than 12 o'clock, the hour of opening at present. In speaking upon it, Mr. Chamberlain said: "The hon. member has failed to realise the peculiar position in which Kew Gardens stand; he treats them as if they existed for the benefit of the inhabitants of Kew. That is not the proper merit or claim the gardens has upon our support, but it is as a great scientific establishment. We are very justly proud of the gardens. I have seen almost every botanical garden in Europe, and I think I am right in saying there is nothing in the whole of Europe which can hold the candle to Kew. I am not speaking as to the decoration of the gardens, but as to their scientific value. There is nothing peculiar in Kew Gardens opening at 12 o'clock. A great number of foreign institutions open at 12 o'clock, and some do not open until late in the afternoon. But the point is that if the gardens were opened at the time the hon. member desires they should be opened, we should most materially interfere with their value as a scientific institution, and should interfere with the work of the officials. In my capacity as Colonial Secretary I am continually applying to Kew in reference to the cultivation of all kinds of plants, and I do not hesitate to say that some of the great improvements made in the Mauritius and some of the West Indian Islands are due almost entirely to the advice and assistance received from the Kew officials. It is not fair to attack public servants who are really performing useful duty, and it is not fair to throw on them duties which would detract from their value as advisers of the colonial and other officers of the Government who may from time to time have occasion to apply for their services." Mr. Burns afterwards remarked that his object in urging the opening of Kew Gardens at an earlier hour than 12 o'clock was not only in the interests of visitors to London, but on behalf of the large body of young men and young women who were studying botany and kindred subjects at the polytechnics. Mr. Gladstone said that it was desirable to extend the privilege of visiting Kew Gardens to as many people as possible; but the question was not so simple as was supposed. He had gone into the matter fully when he was First Commissioner of Works, and he found that when the gardens were opened on Bank Holidays at an earlier hour than 12, comparatively few people availed themselves of the privilege. He did not think that sufficient advantage would result from this arrangement to balance the extra cost which would be involved. But it might be possible to give more facilities to societies and students to visit the gardens under special permission. In replying to the suggestions that the gardens should be opened at an earlier hour for students, Mr. Akers-Douglas said that there could be no doubt that arrangements might be made in that direction. He had made special inquiries, and he found that any one wishing to visit the gardens early for scientific purposes was never refused admission. If institutions, such as those which had been mentioned, wished for the purposes of study to visit the gardens, he was sure that they would be admitted, and more than that, he would take care that they should be admitted.

The second annual congress of the South-Eastern Union of Scientific Societies will be held at Tunbridge Wells on Friday and Saturday, May 21 and 22, under the presidency of the Rev. T. R. R. Stebbing, F.R.S. Particulars can be obtained from the Hon. General Secretary, Mr. George Abbott, Tunbridge Wells.

A meeting of the Institution of Mechanical Engineers will be held on Wednesday evening, April 28, and Friday evening, April 30. The chair will be taken by the President, Mr. E. Windsor Richards. The following papers will be read and discussed, as far as time permits:—"Mechanical Propulsion on Canals," by Mr. Leslie S. Robinson (Wednesday); "Experiments on Propeller Ventilating Fans, and on the Electric Motor driving them," by Mr. William George Walker (Friday).

The following are among the lecture arrangements at the Royal Institution after Easter:—Dr. Tempest Anderson, four lectures on Volcanoes (the Tyndall Lectures); Dr. Ernest H. Starling, three lectures on the Heart and its Work; Prof. Dewar, three lectures on Liquid Air as an Agent of Research. The Friday evening meetings will be resumed on April 30, when a discourse will be given by Prof. J. J. Thomson on Cathode Rays; succeeding discourses will probably be given by Prof. Harold Dixon, the Right Hon. Lord Kelvin, Prof. H. Moissan, Mr. W. H. Preece, and Mr. William Crookes.

Efforts are being made to establish a national photographic record and survey collection, to be under the direction and in charge of the authorities of the British Museum. It is proposed to form a preliminary Committee to organise the work, and to invite to act upon it representatives of the Royal Society, the Society of Antiquaries, the Royal Photographic Society, the Royal Institute of British Architects, the Royal Archæological Institute, the Royal Geographical Society, the Trustees of the British Museum, and others.

On Easter Monday the 129th meeting of the Yorkshire Naturalists' Union will be held at Boston Spa, for the investigation of the banks of the Wharfe, from Flint's Mill to White Crag. We take the opportunity afforded by this announcement to call attention to the admirable leaflets which the Union issues to the members previous to its meetings. The circular before us points out the most important features of the geology, botany, vertebrate zoology, conchology, and entomology of the district to be visited, and is altogether a business-like and helpful production. Many natural history societies would do well to take the methods of the Yorkshire Naturalists' Union as their pattern.

A very fine specimen of an egg of the Great Auk was sold by auction at Mr. J. C. Stevens' rooms on Tuesday. Bidding began at 100 guineas, and reached 280 guineas, at which price the egg was secured by Mr. T. G. Middlebrook.

At a recent special meeting of the Royal Scottish Society of Arts, says the *Electrician*, a report by the Committee appointed to adjudicate on the electric meters that had been submitted in competition for the special Keith prize of 50*l.* was read. Nine meters were sent in. These were tested at the Edinburgh central station with continuous and alternating currents. The Committee were of opinion that while several of the meters possessed many points of novelty and ingenuity which might be capable of further development, none of them were of sufficient merit to warrant the Society in making any award.

We learn from the *Times* that the Council of the Royal Geographical Society have awarded the annual honours as follows:—The Founder's medal to M. Semenoff, Vice-President of the Russian Geographical Society; the Patron's medal to Dr. George M. Dawson, C.M.G., F.R.S., Director of the Geological Survey of Canada; the Murchison grant to Lieutenant Seymour Vandeleur, D.S.O., for his journey of 900 miles in Somaliland and along the Abyssinian frontier in 1893–94; for making surveys of 2073 miles of routes in Uganda, Unyoro, and on the Upper Nile, in 1894–96; and for astronomically surveying 200 miles of practically unknown country in the Niger region, and surveying the new road to Bida and Ilorin from Jebba. The Gill memorial to Mr. C. E. Douglas, for persistent explorations on the western slopes of the New Zealand Alps, extending over twenty-one years

(1874-95); the Cuthbert Peek grant to Dr. Thorvald Thoroddsen, who since 1882 has been continuously exploring Iceland, having at various times covered nearly the whole island; the Back grant to Lieutenant Ryder (of the Danish Navy), for his explorations in East Greenland in 1891 and subsequent years, during which he made important rectifications on the coast, discovered a new series of fjörds, and made important meteorological observations. The following have been elected Honorary Corresponding Members of the Royal Geographical Society:—Prof. G. Della Vedova, Secretary of the Italian Geographical Society; Baron Toll, Russian explorer of the new Siberian islands; and Captain Otto Irminger, President of the Danish Geographical Society.

THE science of experimental psychology, which is zealously pursued in Germany, in the United States, and elsewhere, clearly deserves more attention in this country than it has hitherto received, and it is now proposed that facilities should be afforded for its study at University College. With this object in view a meeting, at which a number of representative men of science were present, was recently held; and a resolution was unanimously adopted expressing the conviction "That, in the opinion of this meeting, it is eminently desirable to establish a laboratory for experimental psychology in University College." An organising Committee, consisting of Mr. Francis Galton, F.R.S., Dr. W. H. R. Rivers, Prof. G. Carey Foster, F.R.S., Prof. Karl Pearson, F.R.S., Prof. E. A. Schäfer, F.R.S., Prof. J. Sully (Secretary), was formed to inquire into the probable cost of the undertaking, and to send out a letter inviting contributions. As the Professors of Physics and Physiology at University College think it possible that they will be able to afford accommodation, at least temporarily, in their laboratories for the teaching of this subject, and that they could assist to some extent by the loan of apparatus, the work could be established at comparatively small cost. It is estimated that an outlay of about 100*l.* would suffice, in the first instance (with the loan of existing apparatus), to provide the equipment necessary for a small laboratory. It is considered, further, that at the outset it may be wise not to attempt more than a course of instruction extending over one term in the year, and that an annual sum of about 100*l.* would enable the Committee to secure the services of an instructor for a single term in each year, and to commence work. For funds to do this the Committee have made an appeal for help to those who are interested in psychological investigations. Cheques should be sent to the London and South Western Bank, Limited, Hampstead Branch, 28, High Street, Hampstead, N.W., to the account of the "Psychological Laboratory, University College."

LIEUT. PEARY'S plan to reach the North Pole has been approved by the American Geographical Society. It has recently been explained by him as follows:—He wishes to proceed along the west coast of Greenland to the northernmost settlement, and there secure five or six young married couples to establish a new settlement as far north as the steamer can conveniently proceed, probably on some island in the Archipelago, and within the distance of 360 miles from the Pole. The settlement will be provisioned for three years, and will include only one, or perhaps two whites, besides himself. All will live together in Eskimo fashion, and will await, for years if necessary, a condition favourable to making the journey over ice on sleds, which can be accomplished at the rate of ten miles a day, so that seventy-two days will suffice to go and return. The ship is to visit the station every year with fresh stores of provisions, but the stock on hand will suffice to support the party in case of failure to reach them for one year, or even two. The expense of the undertaking, if protracted for several years, is estimated at less than 150,000 dols., with a probability of very large reduction from this amount if success is soon attained.

IT is understood (states the *Times*) that the order recently promulgated by the Board of Agriculture concerning the muzzling of dogs in the metropolitan area is only the first step in a comprehensive scheme for giving effect to the recommendation of Mr. Whitmore's Departmental Committee, "that the time has come and the circumstances are opportune for the Board of Agriculture to make a determined and systematic attempt to stamp out rabies." In view of the expression of opinion placed on record by the Committee that such an attempt "will not involve universal muzzling, inasmuch as there are districts where rabies have never appeared," but that the Board of Agriculture "should have regard to the country as a whole, and should impose muzzling over considerable areas, irrespective of the boundaries of boroughs and counties," it is obvious that great discrimination must be exercised in determining the districts in which precautionary measures are needed. From the reports which Mr. Long has received, however, it is clear that London is not an exceptional case; and a muzzling order may shortly be looked for, embracing the whole of South Lancashire and possibly a portion of Cheshire as well. Another area likely to be scheduled at no distant date is that of which Birmingham is the centre.

WHEN mine host in the ideal country inn, which all of us seek but none of us find, brings up a bottle of crusted wine covered with cobwebs and dust, this outward and visible sign is taken as convincing evidence of age. We grieve to have to record that the trust may now be misplaced. A *Bulletin* (No. 7) of the Division of Entomology of the U.S. Department of Agriculture says that in France and Pennsylvania an industry has recently sprung up, which consists of the farming of spiders for the purpose of stocking wine cellars, and thus securing almost immediate coating of cobwebs to new wine-bottles, giving them the appearance of great age. This industry is carried on in a little French village in the Department of Loire, and near Philadelphia, where *Epeira vulgaris* and *Nephila plumipes* are raised in large quantities and sold to wine merchants at the rate of ten dollars per hundred. This application of entomology to industry is one which will not be highly commended.

THE immense advance that has taken place in the accommodation provided for large vessels at the principal ports of this kingdom, may be realised by drawing attention to the fact that a steamship is now under construction which is to be 25 feet longer than the *Great Eastern*, which proved such a white elephant to all who had to do with her, owing to her size and draught, that she was finally broken up and sold for old metal. The *Oceanic*, now under construction by Messrs. Harland and Wolff, at Belfast, for the White Star Fleet, is to be 704 feet in length, or 65 feet longer than any other steamer yet built, and her gross tonnage will exceed 17,000 tons. It is anticipated that she will maintain an average speed of 20 knots, or over. This vessel would be able to steam, in case of need, 23,400 miles at 12 knots an hour, or practically round the world, without coaling.

THE specification of the patent taken out in the names of the late M. Dansac and M. Chassagne, for the process of producing photographs in colour, is reprinted in the current number of the *British Journal of Photography*. It will be remembered that the process was described as based upon the property of selective colour absorption superinduced by (1) treating the plate upon which the negative was taken with a special solution; and (2) treating the positive print with the same solution, the successive application of the blue, red, and green colouring solutions producing the natural colour effect on the print. Our contemporary points out, however, that there is no

reference in the inventors' description to the treatment of the negative or the unexposed plate with any special solution. The process appears to consist in treating a silver print or glass transparency with five specially prepared solutions, the compositions of which are described in the specification.

Those who have studied rocks from the point of view of their magnetic properties, have long been aware of the existence of certain isolated portions, or zones, endowed with intense magnetisation, the distribution of which, in general, bears no fixed relation to the direction of the earth's magnetic field. The theory, frequently advanced, that these singular points owe their magnetisation to discharges of lightning, has received a remarkable confirmation at the hands of Dr. G. Folgheraiter. As the result of numerous observations of the remains of walls and ancient buildings in the Roman Campagna, Dr. Folgheraiter finds that these structures frequently exhibit singular points and zones in every respect identical with those observed in rocks. The presence of singular *points* in walls might be accounted for by supposing that they had existed in the stone before it was used for building; but this explanation is incapable of accounting for the singular *zones* in which a number of adjacent stones, as well as the mortar connecting them, were found to be so powerfully magnetised, that even a small detached portion of the mortar was capable of deflecting a compass-needle through 180°. These zones could only have derived their magnetisation after the wall had been built, and the presence, in some cases, of cracks down the wall in the neighbourhood of the singularities, such as would be caused by lightning, tends to confirm the present theory of their origin.

The classification of cubic curves is due to Newton; but while many papers dealing with curves of the fourth degree are to be found in various mathematical periodicals, these have usually left the appearance of the curves largely to the reader's imagination. We have, therefore, much pleasure in calling attention to a dissertation by Dr. Ruth Gentry, of Bryn Mawr College, "On the Forms of Plane Quartic Curves" (New York: Press of Robert Drummond, 1896), containing a complete enumeration of the fundamental forms of these curves, and thus achieving for quartic curves what Newton accomplished for cubics.

The papers read before the London Mathematical Society from November 1895 to November 1896, have just been published in vol. xxvii. of the Society's *Proceedings*. As we regularly give a brief account of the meetings of the Society, it is unnecessary for us to do more now than call attention to the publication in full of the papers referred to in our reports.

Among the eight valuable papers in the new number of *Science Progress* (April) is one, by Prof. E. B. Poulton, on "A Remarkable Anticipation of Modern Views on Evolution." It clearly appears from the article that James Cowles Prichard, distinguished for his researches in anthropology and etnnology, must be given a very important place among the pioneers of evolution. The second volume of his "Researches into the Physical History of Mankind" (second edition, 1826) contains a most interesting contribution to the history of evolution, and it seems to have been overlooked entirely until Dr. Maurice Davis called Prof. Meldola's attention to it. A careful examination of the work leads Prof. Poulton to conclude that "Prichard apprehended with perfect clearness that domesticated races of animals and plants have been produced by the selection of man, and not by favourable surroundings, careful training or cultivation. He believed in the possibility of organic evolution, and supported it by excellent arguments which still have the strongest weight to-day. He even recognised the operation of natural selection, although he assigned to it a subordinate *rôle*. The most important anticipation is, however, the masterly discussion on the transmission of acquired characters, a discussion in which the distinction between acquired and inherent or congenital characters is clearly drawn, and many of the most difficult cases are fully argued out, the conclusions reached being those independently arrived at by Prof. Weismann over half a century later."

A very good portrait of Darwin, reproduced from a photograph by Mrs. J. M. Cameron, forms a supplement to the current number of the *Academy* (April 10).

The *Journal of Botany* for April gives an interesting sketch, and a portrait, of the life of Mr. H. Boswell, of Oxford, the bryologist, who died on February 4, in his sixtieth year.

We learn, from the *Journal of Botany*, that the Foreign Office has issued a Report on the Botanical Aspects of British Central Africa, by Mr. Alexander Whyte, treating of the economical side of the subject.

The methods in which the natives of New Caledonia cultivate yams and taro is described by M. Glaumont in *L'Anthropologie* (1897, Tome viii. p. 41). To irrigate the latter, long, wide ditches are dug of varied form; some are in spirals, others quite labyrinthiform.

As examples of results obtained by means of a pin-hole camera, some photographs reproduced in the *Amateur Photographer* (April 2) are remarkably good. The pictures accompany two articles, by Mr. George Davison and Mr. H. C. Shelley, on pin-hole cameras and their use.

Herr J. Brunnthaler, of Vienna, has issued a very copious "Jahres-Katalog" of the Vienna *Kryptogamen-Tauschanstalt*, in German, French, and English, consisting of a very long list of species in the various families of Cryptogams offered in exchange or for purchase. The locality of the collection is in all cases given, and several new species of Fungi are described.

We have received the Annual Report of the Royal Botanic Gardens, Trinidad, for 1896. Among interesting items of information is the rediscovery in the island of *Sacoglottis amazonica*, thus establishing the source of one of the "drift fruits" discussed in the Reports of the *Challenger* Expedition, as being found by various collectors in the Caribbean and other seas.

Prof. W. A. Herdman, who has done a little work in prehistoric archæology in the Isle of Man and elsewhere, threw out the suggestion, at a recent meeting of the Liverpool Biological Society, that the "Calderstones" near Liverpool originally were part of a dolmen; a visitor present on that occasion corroborated this view, and the evidence has since been collected by Prof. Herdman in the *Transactions* of that Society.

A Mykenæan painting on a calcareous slab is described by M. Salomon Reinach in *L'Anthropologie* (1897, Tome viii. p. 19). It represents five marching warriors, who carry circular shields, and who are poising their javelins as if on the point of throwing them; below are five ill-drawn animals. M. Reinach hopes that it will soon be possible to clearly distinguish between Achæan and Ægean or Pelasgian finds. He refers the painted slab to the former culture.

The study of iron carbide has for a long time occupied the attention of chemists, the general result of whose researches has been to show that steel contains a crystalline carbide corresponding to the formula Fe_3C. Curiously enough, although this was one of the first metallic carbides known, it has proved to be the last to be prepared in quantity by direct synthesis. When pure iron and carbon are melted together in the electric

furnace and allowed to cool slowly, the ingot contains only about 1 per cent. of combined carbon, although the presence of a considerable quantity of graphite shows that the mass, when fluid, contained a much higher percentage. In preparing diamonds by rapidly cooling a solution of carbon in iron, M. Moissan noticed, in the central portion of the casting, signs of crystallisation recalling the appearance of the boride and the silicide of iron. It thus appeared probable that the carbide of iron could exist at a very high temperature, but was almost completely decomposed on slowly cooling to the solidifying point of the casting. Following up this observation, M. Moissan heated pure iron for three minutes in a carbon crucible with a current of 900 amperes at 600 volts, the mass being then taken from the furnace and poured directly into cold water. The ingot was crystalline in structure, containing from 3 to 4 per cent. of combined carbon, but no graphite. From this the carbide was separated, by a modification of the method of Mylius, Foerster and Schwenz, in brilliant crystals of exactly the composition Fe_3C (*Comptes rendus*, April 5). Water has no action upon this, even at 150°, but hydrochloric acid gives a mixture of hydrogen and methane. The experiment is stated by M. Moissan to be free from danger, but is hardly likely to be frequently repeated in the laboratory on account of the enormous currents required, representing, indeed, upwards of 700 horse-power.

FATHER SIDGREAVES has issued his report on the meteorological, magnetic, and other observations made at the Stonyhurst College Observatory in 1896. It is curious that the instruments at Stonyhurst seem to object to furnish positive evidence of phenomena, either terrestrial or celestial. Tracings of the horizontal magnetic direction and force were examined in connection with several distant earthquakes; but Father Sidgreaves says he has found nothing in the movements of the magnets that could be attributed to any but magnetical disturbance. Even the nearer earth tremor of December 17, 1896, made no impression on the Stonyhurst magnetic curves. Over 350 photographs of stellar spectra were obtained during the year with the compound prism spectrograph in combination with the Perry-Memorial objective.

AN admirable series of leaflets on birds, edited by Mr. H. E. Dresser, has been published by the Society for the Protection of Birds. Part I. contains short and popular articles, written by well-known ornithologists, on owls, woodpeckers, starling, swallows, kingfisher, osprey, dippers, nightjar, titmice, kestrel, and plovers. The leaflets will do good service in interesting the public in our feathered friends, and in preventing the wanton destruction and possible extermination of beneficial species. At the end of the collection of leaflets is a concise and clear statement of the Acts and Orders which have been made for the protection of eggs and birds in the different counties.

THE following new editions of scientific works have recently been published:—"Stones for Building and Decoration," by George P. Merrill. (New York: Wiley and Sons. London: Chapman and Hall.) This book has already been reviewed in NATURE (vol. xlv. p. 222, 1892); the present edition, however, contains over fifty more pages than the original. It deals almost entirely with stones found in North America, or imported, and used in the United States for building and ornamental purposes.—"Collected Contributions on Digestion and Diet," by Sir William Roberts, F.R.S. Second edition. (London: Smith, Elder, and Co.) All the contributions the author has made, either in the form of lectures or papers, to subjects relating to digestion, dietetics, and dyspepsia, are brought together in this volume. An article on the opium habit in India, which appeared as an "annexure" to the Report of the Royal Commission on Opium (1895), has been appended to the new edition.—The eighth edition of an "Elementary Text-book of Physics," by Prof. W. A. Anthony, Prof. C. F. Brackett, and Prof. W. F. Magie, has been published by Messrs. Wiley and Sons. The book contains a concise and instructive statement of the fundamental principles of physics. It possesses many good features, and may be used with advantage as a text-book of physics for the higher classes in schools and colleges.

THE Cambridge University Press will publish very shortly: "The Life-Histories of the British Marine Food-Fishes," by Dr. W. C. McIntosh, Professor of Natural History in the University of St. Andrews, and Mr. A. T. Masterman, Assistant Professor and Lecturer in Natural History in the same University.

THE additions to the Zoological Society's Gardens during the past week include a Chacma Baboon (*Cynocephalus porcarius*, ♂), a Levaillant's Cynictis (*Cynictis penicillata*), a Jackal Buzzard (*Buteo jacal*), a Cape Grass Owl (*Strix capensis*), two Hoary Snakes (*Pseudaspiscana*), two Yellow Cobras (*Naia flava*), a Puff Adder (*Bitis arietans*) from South Africa, presented by Mr. J. E. Matcham; a Red-footed Ground Squirrel (*Xerus erythropus*) from West Africa, presented by Sir Archibald Lamb; a Larger Tree Duck (*Dendrocygna major*) from India, presented by Mr. W. Jamrach; two Barbary Turtle Doves (*Turtur risorius*) from Africa, presented by Mr. W. S. Berridge; a Crested Porcupine (*Hystrix cristata*) from West Africa, an Argus Pheasant (*Argus giganteus*, ♀) from Malacca, a Red and Blue Macaw (*Ara macao*) from South America, an Indian White Crane (*Grus leucogeranos*) from India, deposited; four Tufted Ducks (*Fuligula cristata*), European; two Red-backed Buzzards (*Buteo erythronotus*) from South America, two Barred-shouldered Doves (*Geopelia humeralis*) from Australia, purchased; a Markhoor (*Capra megaceros*, ♂) from North-east India, received in exchange; a Mouflon (*Ovis musimon*, ♂), four Coypu Rats (*Myopotamus coypus*), born in the Gardens.

OUR ASTRONOMICAL COLUMN.

OBSERVATIONS OF JUPITER'S FIFTH SATELLITE.—Prof. J. M. Schaeberle, writing from the Lick Observatory to the *Astronomical Journal* (No. 398), gives the results of his observations relating to the fifth satellite of Jupiter. These measures will furnish considerable data for correcting the mean motion of the satellite, even if no other observations be secured at the present season. Marth's ephemeris was found still to be in good agreement with the observed place, the error in time of elongation being less than four minutes. The observations were made on February 27 of this year, and were begun within half an hour of the satellite's greatest elongation.

HARVARD COLLEGE OBSERVATORY REPORT.—We have received the fifty-first annual report of the director of the Astronomical Observatory of Harvard College, Prof. E. C. Pickering, to the president of the University. A glance at this shows one what an immense amount of useful work is being done at this observatory, and how great a scope is included in it. The two subjects to which special attention is called, are the successful erection of the Bruce photographic telescope in Peru, and the establishment of a series of circulars, which have for their object a prompt means of announcing discoveries made at the observatory or its branch stations, and other similar matters of interest. The usual routine work has been continued with the well-known energy displayed by the director in all departments. Thus with the East equatorial, among other observations, 4192 comparisons have been made to determine the form of the light curve of the Algol variable W Delphini, 3436 of U Cephei, and 1616 of Z Herculis and 1748 of T. Andromedæ. The photographs taken with the 8-inch Draper telescope numbered 2508, while the 8-inch Bache telescope has been employed in obtaining 2770 stellar spectra. Among these many very interesting objects have been discovered, several of which have been previously referred to in these columns. The 13-inch Boyden tele-

scope, situated at Arequipa, has also been very extensively used, the chief work being the photography of the spectra of the brighter southern stars with one, two, and three prisms. The report further describes the work done at the meteorological stations, and concludes with a brief summary of the recent publications, and those which are in or nearly ready for press.

THE INTERNATIONAL UNIFICATION OF TIME.—The question of France adopting Greenwich time, or, as they would prefer to call it, Paris time, minus nine minutes twenty-one seconds, seems to be still in the air. Nearly all other countries have come into line on the subject, with the exception of Spain and Portugal. These last-mentioned would, no doubt, soon complete the harmony if only France would take the lead. England, Belgium, Holland, and Luxemburg possess to-day West European time. Central European time is adopted by Italy, Switzerland, Germany, Denmark, Norway and Sweden, while Russia (nearly to one minute), Roumania, Bulgaria, and European Turkey use Eastern European time. In Japan the legal time is nine hours in advance of Greenwich, and in Australia and New Zealand the time zones used are 8, 9, 10, and 11 hours earlier than Greenwich. Canada and the United States have for some years used four zones, namely, 4, 5, 6, 7, and 8 hours behind Greenwich time. An article summing up the information on this question of time is contributed to the *Revue Scientifique* (No. 14, April 3), and the question of the advisability of adopting Greenwich time is strongly advocated by the writer, M. Ch. Lallemand. In his summary he mentions the probable motives that have led M. Boudenoot, deputy of the Pas-de-Calais, to submit to the Chamber the following proposition, which is more simple than that which has been previously suggested, namely: "The legal time in France and in Algeria, is the mean time of Paris retarded by nine minutes twenty-one seconds." The writer's concluding words are: "Reduced to this and stripped of all which could hurt the susceptibilities of the most delicate, one may hope that this projected reform will meet with the reception that it deserves, both by Parliament and the public; that is to say, the unanimous approval of *tous les hommes de progrès*."

KOCH'S RECENT RESEARCHES ON TUBERCULIN.

DURING the last couple of weeks there have appeared in the various lay and medical journals long accounts of an improved method of preparing and using tuberculin. Koch and his assistants, no doubt disappointed at the results of the premature application of the tuberculin treatment, have, for seven years, worked away steadily to try to counteract some of the damage done by irresponsible enthusiasts in 1890. How far they have succeeded will be gathered by those who carefully weigh the work that has now been published. Disregarding Koch's instructions that the cases of tuberculosis to be subjected to the tuberculin treatment should be carefully selected, and that tuberculin should not be tried in any but comparatively early cases, physicians threw aside tuberculin as being not only of no use, but absolutely injurious, and taking into consideration the class of case on which it was tried they were right. The febrile reaction may or may not have been injurious in the majority of cases, but in a certain proportion it was undoubtedly associated with exacerbations of the disease and a general deterioration in the condition of the patient. A few workers, however, have all along maintained that in properly selected cases the exhibition of tuberculin has undoubtedly proved beneficial, whilst as a diagnostic agent, especially in tuberculosis of cattle, it has opened up the possibility of gradually eliminating tuberculosis from our farms and dairies. Tuberculosis, however, has never been brought into line, as regards the production of immunity, with tetanus, anthrax, diphtheria, and certain similar diseases. But a step in advance in this direction has now been made by Koch, as is evidenced by the publication of his most recent work. He points out that in the case of tubercle, unlike many other diseases, an infection, in place of protecting, rather predisposes to new attacks of the disease. On the other hand, there appear to be certain conditions, such as those met with in acute miliary tuberculosis, under which the tubercle bacilli disappear; from this he argues that immunisation only takes place when, as in general tuberculosis, the whole body is invaded by great masses of tubercle bacilli, which thus come in contact with comparatively healthy tissues. Having determined this, it becomes necessary to find out whether the products of the bacillus failing to give immunity, the substance contained in the bodies of the bacilli are the immunising agents. By means of a decinormal soda solution, he partially broke down, or extracted, the tubercle bacilli; with the fluid thus obtained (T.A., or alkaline tuberculin), he made a series of injections, and found that this substance acts very much as did his original glycerine tuberculin, producing both local and general reactions, but acting more powerfully; and he found that relapses were undoubtedly less frequent when this substance was used than when the original tuberculin was injected. If the remains of the bodies of the tubercle bacilli were left in this fluid, abscesses were formed when large quantities were injected, but such abscess formation was immediately prevented when the fluid was filtered. The tuberculin in this form, however, required to be used in a fresh condition, and, therefore, could not be applied on any very extensive scale. The bodies of tubercle bacilli he found are covered with a layer containing two sebacic (fatty) acids, one of which is soluble in dilute alcohol, and is easily saponified; the other, soluble only in boiling alcohol or ether, is not so readily saponified. These fatty acids form a layer which protects the bacillus, and prevents its being absorbed from the seat of injection, with the result that it remains and sets up a powerful local suppurative reaction. By pounding these organisms in a dry condition, then adding distilled water and centrifugalising, then by drying the sediment and repounding until the whole of it is dissolved, Koch has been able to obtain the substances of the bodies of the bacilli in an absorbable condition. These substances, he says, appear to be divided into two sets: those contained in a whitish, opalescent, transparent supernatant fluid, which contain no bacilli, and a muddy deposit, which contains the solid bacilli. The upper layer contains most of the substance soluble in glycerine. This upper layer is very like the ordinary tuberculin, and acts like that substance, but more powerfully; whilst the lower layer, or the tuberculin remainder (T.R.), has an even more distinct immunising effect. Used in very large doses it produces a general reaction (rise of temperature, loss of appetite, &c.); but used in smaller doses, gradually increasing as quickly as the patient's condition will allow, and avoiding a general reaction, it sets up an immunity against the T.R. substance; indeed, Koch shows that any case which can be rendered proof against T.R. can also be rendered proof against the tubercle bacillus itself. Without going into the question of dosage, it may be insisted that this substance should never be given so as to produce a rise of temperature of more than half a degree. If the disease is advanced the substance appears to exert little or no effect, but as a protective agent and as a curative agent applied at an early stage of infection, a certain proportion of experimentally infected guinea-pigs could be beneficially influenced. So far, as with tuberculin, the best results have been achieved with cases of lupus (or skin tubercle), and here the improvement obtained has been far greater than that produced by the use of tuberculin, though Koch guards his position by saying that though many of the cases may be regarded as cured in the ordinary sense of the word, it is, he thinks, premature to use the word cure before a sufficient time has passed without a relapse. It is, however, important to note that in none of the numerous cases treated were the patients injuriously affected. There was a steady increase in weight, and the variations of temperature, so marked in the tubercular patient, were distinctly diminished, and the general condition of the patient improved.

The interest that attaches to these experiments does not end at this point, for it is evident, if an immunity against the action of the bacilli and their poisons can be obtained, that the treatment of tubercle may ere long be brought into line with the treatment of some of the other specific infective diseases, and that by an extension of Koch's and Maragliano's methods still further advances in the treatment of tubercle may be made. What will strike those who have followed the development of Koch's method of treatment from the time that he discovered the bacillus to the present moment, is the ingenuity, perspicacity, and tenacious adherence to one idea that has characterised the whole of Koch's reasoning and experiments. It is not too much to say that through his early work we have the hope that tuberculosis may gradually be eradicated from cattle, whilst as the result of his later experiments there appears to be some promise that for the human subject protection against the ravages of tuberculosis and even cure may be obtained.

G. SIMS WOODHEAD.

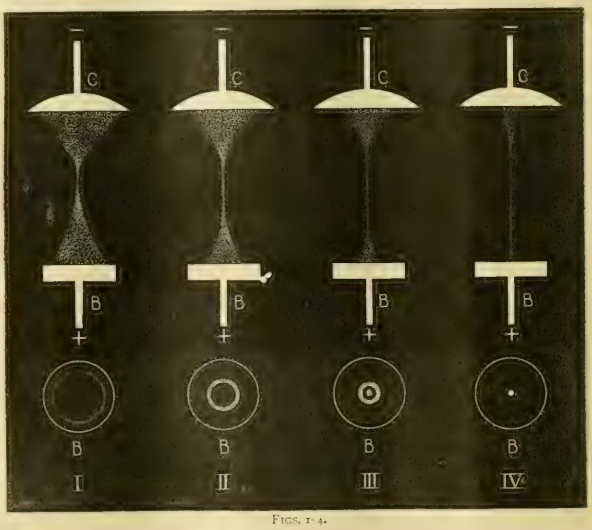
SOME EXPERIMENTS WITH KATHODE RAYS.[1]

THE extensive employment of the focus form of Crookes' tubes as the most efficient known means of generating X-rays, has rendered advisable the more complete investigation of the kathode ray discharge in tubes of this description.

Hitherto, the usual method of investigating the characteristics of a kathode ray discharge apart from its mechanical properties, and beyond what is visible to the unassisted eye, has been by allowing the rays to fall upon a screen of some brightly fluorescent material, such as glasses of various descriptions, or screens covered with fluorescent salts. With all of these the maximum amount of fluorescence appears to be produced by such comparatively weak kathode rays, that in some cases the special effects produced by the more powerful rays seem to be more or less entirely masked, while the well-known phenomenon of the fatigue of fluorescent substances, when exposed to the more active rays, conduces to the same result.

Surface Luminescence of Carbon when exposed to Kathode Rays.

I have found in some cases that by replacing the usual screen, made of or covered with fluorescent material, by one of ordinary electric light carbon, much appears which was previously invisible. When a concentrated stream of powerful kathode rays are focussed upon a surface of carbon in this manner, a very brilliant and distinctly defined luminescent spot appears on the surface of the carbon at the point of impact of the rays, the remainder of the carbon remaining black. This luminescent spot seems to have a very close relation to the fluorescent spots on glass and on other fluorescent materials under similar influence. The effect is evidently a purely surface effect, as when the kathode stream is rapidly deflected by means of a magnet, the luminescent spot on the carbon moves with no perceptible lag. Further, though, as is also the case with glass, the whole of the carbon becomes gradually heated to a considerable extent if much power be employed for a long period of time, these luminescent spots are instantaneously produced on carbon of very considerable brilliancy with but a comparatively low power. Again, just as glass is known to become fatigued under the influence of kathode rays, so that after a time it refuses to fluoresce so brightly as before, so carbon is similarly fatigued, though only after having been very strongly acted upon. Carbon, like glass, also recovers its property of giving a surface luminescence to some extent, though it does not seem to entirely recover, at any rate, at all rapidly.



FIGS. 1-4.

Apparent form of the Kathode Ray Discharge in a Focus Tube.

As is well known, in tubes of the ordinary focus type with a single spherical concave kathode, the rays coming off normally to the kathode surface appear to converge in more or less of a cone to a focus, and if the vacuum be not too high, to diverge again immediately in another cone upon the other side of the focus. At higher vacua the rays, after passing the focus, do not appear to diverge again at once, but seem to form themselves into a description of thread which connects the convergent and divergent cones, and is longer or shorter according as the vacuum is higher or lower. The focus, or perhaps more correctly, the point at which this thread commences, seems always to be more distant from the kathode than the centre of curvature of the latter, but the variation in this respect seems to be less and less the higher the exhaustion. This is no doubt due to the mutual repulsion of the rays, and accords with the assumption that the rays consist of charged particles, which travel more and more rapidly the higher the exhaustion. Probably for the same reason, kathodes that are only slightly concave, focus further in proportion beyond their centres of curvature than do deeply concave kathodes, for the same vacuum.

Apparent Hollowness of the Divergent and Convergent Cones of Rays.

When the divergent cone is thrown upon a thin platinum disc, as in the ordinary focus tube, and sufficient electric power—say, from a 10-in. Ruhmkorff coil—is employed, the platinum quickly attains to a red heat. With platinum, either the whole disc becomes uniformly heated, or in the event of the diameter of the cone of rays where it strikes the platinum being small compared with the area of the platinum, that portion of the platinum covered by the base of the cone becomes uniformly heated to a higher temperature than the remainder. This is as much as can usually be seen with platinum, though rather more is sometimes visible with aluminium; but if instead of either metal the disc is made of ordinary electric light carbon, I have found that the luminescent portion of the carbon, instead of comprising the whole disc, or consisting of a uniformly heated circle, will in some cases take the shape of a brilliantly luminescent and apparently white hot ring, with a well-defined dark, and seemingly quite cold, interior. As the dimensions of the cone of rays are increased or decreased by decreasing or increasing the vacuum, the luminescent ring will be found to increase or decrease correspondingly in diameter, at the same time being brighter when small than when large. Further, when the ring is very small it will usually have a very brightly luminescent central spot, with a dark intervening portion between this spot and the ring, and when the vacuum is further increased the ring will gradually close in upon the spot until only the latter remains.

Figs. 1, 2, 3, and 4 show diagrammatically these hollow effects for four different degrees of vacuum, 1 being the lowest and 4 the highest exhaustion. The upper portion of each of these figures represents the general appearance of the kathode discharge between the spherical concave aluminium kathode C at the top, and the carbon anti-kathode B at the bottom. Beneath each of the elevational views of the kathode discharge will be found a plan view of the carbon anti-kathode, showing for each condition of vacuum the effect of the kathode discharge upon the carbon anti-kathode, in forming a brightly luminescent hollow ring, gradually decreasing in diameter as the vacuum is increased, until it centres on a point, as already mentioned.

[1] Abstract of a paper by A. A. C. Swinton, read before the Royal Society, March 11.

It may further be remarked that the diameter of the luminescent ring may be increased or diminished, or finally reduced to a point, without altering the degree of vacuum, by moving the anti-kathode away from or towards or finally into the focus of the kathode stream, the appearance of the ring in each of these cases being practically similar to those shown in the figures for a uniform distance with varying vacuum. Similarly it may be shown that the converging cone of rays between the kathode and the focus produce hollow rings upon a carbon anti-kathode exactly as does the diverging cone of rays. When the anti-kathode surface is not at right angles to the line of the discharge, the ring, in place of being circular, takes the proper form of a conic section. The holding of a magnet near the tube distorts the ring from a circular shape and moves its position on the carbon.

From these experiments it appears that both the diverging and converging cones of kathode rays act as though they were not of uniform density throughout their sections, but, at any rate, in some instances as if they were completely hollow.

It should, however, be noted that these hollow effects appear only to be obtained with fairly short focus kathodes, such as are usually employed in X-ray focus tubes, that is to say, with kathodes whose diameter is large as compared with their radius of curvature, so that the rays converge and diverge rapidly to and from the focus. With comparatively flat, long focus kathodes the cones do not show any signs of being hollow, and produce a uniformly luminescent spot upon the carbon of larger or smaller diameter, according to the conditions of vacuum and the position of the screen.

For instance, while kathodes 1·125 inches diameter and 0·708 inch radius of curvature gave in the manner described distinctly hollow convergent and divergent cones, a kathode 1 inch diameter and 1·5 inches radius of curvature gave convergent and divergent cones that appeared to be uniformly solid under all conditions.

On the other hand, with rays from flat kathodes brought to a focus by magnetic means, both convergent and divergent cones are found to produce hollow ring effects.

The Rays cross at the Focus with no Rotation.

In order to investigate the kathode rays in a focus tube still further, and more especially in order to discover whether the various rays from the kathode cross one another at the focus, or diverge again without crossing, and also in order to discover whether there is any twist or rotation of the rays, similar to what has been observed in the case of rays focussed by magnetism, a tube was constructed similar to that used in the previous experiments, with a carbon anti-kathode which was also the anode, fixed at the opposite side of the focus from the kathode, with the focus about equally distant between it and the kathode. The peculiarity of this tube consisted in the fact that a sector of the aluminium kathode, equal to one-eighth of the total area of the kathode, had been entirely removed, as shown at C, Fig. 5. It was expected that on using this tube, with the proper degree of vacuum to form a well-defined ring on the anti-kathode screen, that a portion of the ring, corresponding with the amount of the kathode cut away, would be found wanting; and that by the position of this gap in the ring it would be possible to ascertain whether the rays crossed at the focus, and whether there was any rotation. What actually was observed is shown for three different conditions of vacuum in Fig. 5, B being for the highest, and B″ for the lowest vacuum. As will be seen, the expected gap in the ring was obtained, but with the unexpected addition that the dimensions of this gap, instead of being only one-eighth of the circumference of the ring, was seven-eighths of the circumference. In fact, the amount of ring shown corresponded not with the seven-eighths of the remaining kathode surface, but with the one-eighth of the kathode that had been removed. The portion of ring that did appear was of a length corresponding exactly to the arc of the removed sector of the kathode, according to its greater or lesser nearness to the centre with different conditions of vacuum; and as the portion of ring was in each case exactly in line with the portion of kathode that had been cut away, it would appear that there is no rotation of the kathode beam as a whole, that the rays do cross at the focus; and, further, that when the hollow convergent cone is, as it were, split in this manner, some unexplained action, similar in effect to the existence of a circular surface tension, causes the gap to widen out and the remaining portion of the ring-shaped section of the cone to contract correspondingly, without, however, altering its diameter.

In order to further investigate the matter another tube was made, in which the concave kathode was complete; but the interior of the tube was furnished with a small movable piece of aluminium, which by shaking could be moved up and down the tube between the kathode and anti-kathode, and which, while not quite reaching the centre of the tube, would fill up very nearly one quarter of the circular sectional area of the latter.

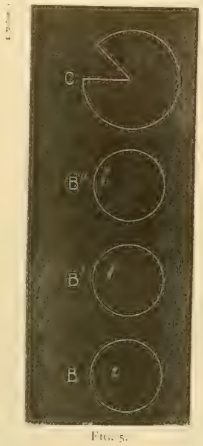


Fig. 5.

With this arrangement of tube, with the aluminium obstacle placed just at the focus, as shown in Fig. 6, the point of the obstacle just missing the kathode rays, a complete ring was formed on the carbon anti-kathode. On moving the obstacle slightly into the divergent cone, exactly one quarter of the ring on the anti-kathode failed to appear, as shown in Fig. 7, and on the obstacle being further moved in the same direction, the result was not altered.

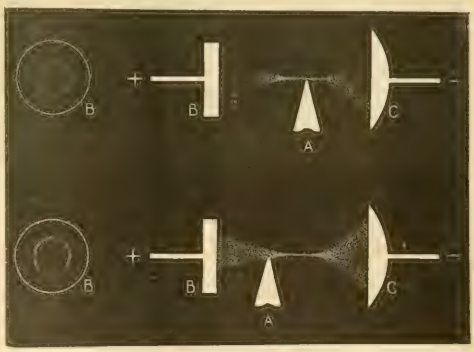

Fig. 6, 7.

As in each of the latter two cases there was no displacement of the gap in the ring, the above showed that there is no rotation of the divergent kathode cone.

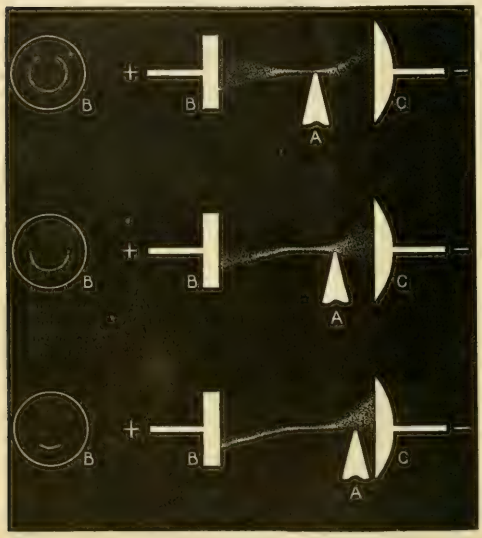
Experiments were next tried with the aluminium obstacle, moved so that its point just entered the converging cone of kathode rays, when a small portion of the ring was cut out; but on the opposite side, as shown in Fig. 8, this confirming the previous experiments, which showed that the rays cross one another's paths at the focus without rotation. Upon moving the aluminium obstacle a little nearer to the kathode, so that

its point entered still further into the convergent kathode beam, one-half of the ring disappeared, as in Fig. 9, while, when the obstacle—which, it should be remembered, blocked only one-quarter of the circular area of the tube—was brought close up to the kathode, only about one-quarter of the ring remained, as in Fig. 10.

Further experiments were tried with the aluminium obstacle both in the divergent and convergent cones, but with the tube exhausted to different degrees of vacuum, when it was observed that when the obstacle was in the divergent cone, a portion of the ring was cut off exactly proportional to the angle subtended by the sides of the obstacle; while when the obstacle was placed in the convergent cone, a much larger proportion of the ring was cut off in each case, this being much more marked with a high vacuum, when the diameter of the ring was small, than with a low vacuum, when the diameter of the ring was large.

The Convergent Cone at Higher Vacua.

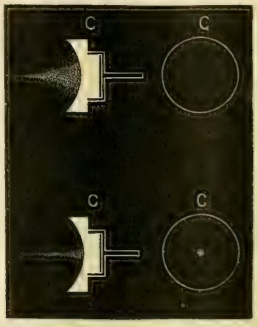
The carbon anti-kathode screen was found useless for investigating the convergent cone of kathode rays at anything but a very low vacuum, by the reason of the well-known difficulty in



FIGS. 8-10.

getting any discharge to pass when the distance between the electrodes is less than the thickness of the dark space; and for the further reason that if the anti-kathode screen was not connected to the anode, it became itself negatively charged, and acted as an additional kathode when brought into the space between the kathode and the focus.

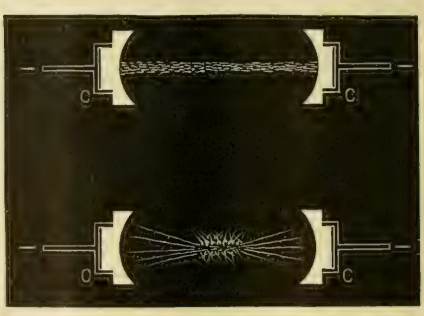
Under these circumstances, it was thought that possibly some additional information might be obtained with regard to the form of the convergent cone at high vacua, by making the concave kathode itself of carbon. A tube was therefore constructed having a concave carbon kathode, the diameter of which was 1 inch, and the radius of curvature 0·75 inch. The appearance of the kathode with this tube is shown for a fairly high vacuum in Fig. 11, in which the kathode itself is shown in section, so as to let the form of the discharge be better seen. As will be observed under this condition of vacuum, which was too high to show any divergent cone, the cone of convergent rays appears to be contracted in diameter at its base, and to come off from the central portion of the kathode only, the remaining surface of the kathode being apparently inactive. This was found to be still more the case at higher vacua, as will be seen from Fig. 12, which shows in a similar manner the form of the kathode discharge in a tube exhausted to a very high vacuum. In this case, as will be observed, the whole of the kathode rays appear to come off from a very small spot in the centre of the kathode. Further, that this small spot is, at any rate, the source of most, if not all, activity, was evident from the fact that it became luminescent exactly in the same manner, but in a less degree, than had previously been observed with a carbon surface upon which kathode rays were concentrated. Whether this surface luminescence of the kathode carbon, at the point where the kathode rays leave it, is due to the violent tearing away of particles of carbon, or to some other cause, it is difficult to say; but the fact that at high vacua the kathode rays come of entirely



FIGS. 11, 12.

—or, at any rate, almost entirely—from only a very small portion of the centre of the kathode, explains the observed fact that, within limits, large kathodes have no advantage over small kathodes in X-ray tubes.

During the carrying out of the above experiments with a carbon kathode, very bright sparks were occasionally seen coming off the kathode and passing through the focus, and it was consequently thought that possibly by placing two concave carbon kathodes facing one another, such particles, by being caused to rebound backwards and forwards continuously between the two, might render the form of kathode stream visible at very high vacua when the stream itself becomes otherwise invisible.



FIGS. 13, 14.

With this view, a tube was made with two concave carbon kathodes, similar to those employed in the last experiment, were placed exactly opposite one another. The anode was placed in an annex, and the two kathodes were connected together by means of a wire outside the tube. At a very high exhaustion, this tube gave very beautiful effects, and showed clearly the form of the kathode discharge at a degree of exhaustion when it is usually in itself quite invisible. Immediately on the current being turned on and the discharge passing, a straight and thin stream of bright golden coloured particles of apparently incandescent carbon passed between small luminescent spots at the

centres of each kathode, as shown in Fig. 13. This did not last for more than a second, when owing, no doubt, to the rapid fall of vacuum the appearance changed to that shown in Fig. 14, and the incandescent particles of carbon could be seen passing backwards and forwards along the convergent and divergent cones of kathode rays, which, at the lower vacuum, proceeded from both kathodes, and spluttering in the centre, where the particles going in opposite directions collided. This appearance lasted for some seconds, becoming gradually fainter as the vacuum fell. By re-exhausting the tube with the pump, however, the original appearance shown in Fig. 13, as also the appearance shown in Fig. 14, could be produced as often as desired. Apparently the particles of carbon become heated to incandescence either by the action of the kathode rays upon them while they are flying through space, or by their friction in passing through the residual gas, and possibly by their mutual collisions, for in the stage shown in Fig. 14, when the kathodes themselves show no luminescence the flying particles appear to be most intensely luminescent when in the centre of the tube. It may be mentioned that after this experiment had been repeated several times, the glass of the tube became perceptibly blackened, which, taken with the fact that a similar tube with kathodes of aluminium showed no stream of bright particles, goes to show that the particles consist of carbon torn off the surfaces of the kathodes.

The Production of X-Rays.

In order to ascertain whether it is necessary that the kathode rays should fall on solid matter in order to produce X-rays, another tube was constructed, similar in all respects to the last, with the exception that the two kathodes were made of aluminium.

It was thought that with this tube the opposing streams of kathode rays might possibly produce X-rays at the point where they met. This does not, however, appear to be the case, as though this tube, when exhausted to so high an extent that the alternative spark in air leapt fully eight inches, gave X-rays in considerable quantity, these rays appear to come entirely from portions of the glass of the tube that were covered with green fluorescence, and not at any rate appreciably from the central point between the two kathodes, where the opposing streams of kathode rays would meet one another.

It seems, therefore, that X-rays can only be produced by kathode rays when these strike solid matter.

No doubt this matter must also be positively electrified.

THE INSTITUTION OF NAVAL ARCHITECTS.

THE annual spring meeting of the Institution of Naval Architects was held last week in the hall of the Society of Arts, under the presidency of the Earl of Hopetoun, President of the Institution. The meeting extended over the 7th, 8th, and 9th of April. The following is a list of the papers read :—

"Recent Trials of the Cruisers *Powerful* and *Terrible*," by A. J. Durston, Engineer-in-Chief to the Royal Navy.

"Water-tube Boilers in War Ships," by Rear-Admiral C. C. P. Fitzgerald, R.N.

"A Mechanical Method of Ascertaining the Stability of Ships," by A. G. Ramage.

"On the Fighting Value of certain of the Older Ironclads if Re-armed," by Captain Lord Charles Beresford, R.N.

"The Application of the Compound Steam Turbine to the Purposes of Marine Propulsion," by the Hon. Charles Parsons.

"On the Use of the Mean Water Line in designing the Lines of Ships," by A. G. Ramage.

"The Accelerity Diagram of the Steam Engine," by J. Macfarlane Gray.

"Acetylene and its Probable Future Afloat," by Prof. Vivian B. Lewes.

"Nickel Steel as an Improved Material for Boiler Shell Plates and Forgings," by William Beardmore.

"Application of Electrical Transmission of Power in Marine Engineering and Shipbuilding," by F. von Kodolitsch.

The papers were mostly of a practical rather than of a scientific interest. Mr. Durston's contribution on water-tube boilers was a valuable record of the performance of the boilers in the two big cruisers lately added to the Navy. It may be said generally that the Belleville boiler has proved successful in these ships, and has done a little better than return-tube boilers of the type recently placed in the ships of Her Majesty's Navy. The fuel economy has been fair, 1·7 lbs. per I.H.P. per hour ; whilst the weight of boiler and contained water was somewhat below that which has been generally reached in Navy return-tube boilers when run under easy conditions ; but in some cases the boiler weights per I.H.P. of other war vessels have been lower than the figure—22 I.H.P. per ton—recorded of the two cruisers. In the long debate which followed the reading of the paper, it was stated that the Belleville boiler appeared to advantage in the *Powerful* and the *Terrible*, because it was compared with a type of boiler that was ill-designed The general opinion of speakers, however, was that Mr. Durston had scored a great success, and deserved to be congratulated on his courage and perseverance. Admiral Fitzgerald discoursed on the advantages of the Belleville boiler from a tactical and strategical point of view. His opinion was altogether favourable to the new type of steam generator. Lord Charles Beresford, in his contribution, advocated the re-arming of certain old battle-ships with modern breech-loading guns, or else scratching them off the list of effective ships. The preponderance of naval opinion appeared to be in favour of the latter course. Mr. Ramage's paper described a mechanical method of ascertaining stability by means of wooden sections representing mean sections. The method is ingenious, but the principle is not altogether new.

The paper by Mr. Parsons had been looked forward to with great interest, as it was to describe a very wonderful boat, which was fitted with the author's steam turbines in place of ordinary engines. The *Turbinia*, as the boat is named, is 100 feet in length, 9 feet beam, and 44½ tons displacement. The original turbine engine fitted in her was designed to develop upwards of 1500 actual horse-power at a speed of 2500 revolutions per minute. The boiler is of the water-tube type for 225 lbs. per square inch working pressure with large steam space, and large return water legs, and with a total heating surface of 1100 square feet, and a grate surface of 42 square feet ; two firing doors are provided, one at each end. The stokeholds are closed, and the draught furnished by a fan coupled directly to the engine shaft. The weights are remarkable, and certainly have never before been equalled for lightness in any practicable marine machinery. They are as follows :—

Main engines	3	tons 13 cwts.
Total weight of machinery and boiler, screws and shafting, tanks, &c. ...	22	tons
Weight of hull complete	15	tons
Coal and water	7½	tons
Total displacement	44½	tons

The great trouble, as might have been expected from the high rate of revolutions, was with the screws, and Mr. Parsons has only repeated the experience of Mr. Thornycroft with his destroyer, in finding that in all screws there is a limiting speed of blade, due to cavitation, depending upon the slip ratio and the curvature of the back. In order to throw light on this subject, the author had recourse to an ingenious device. Model screws were revolved in a bath of hot water heated to within a few degrees of the boiling point, and in order that the model screw should produce analogous results to the real screw, it was arranged that the temperature of the water and the head of water above the propeller, as well as the speed of revolution, should be such as to closely resemble the actual conditions and forces at work in the real screw, the object in heating the water being to obtain an increased vapour pressure from the water, so as to permit a representation of the conditions with a more moderate and convenient speed of revolution than would otherwise have been necessary. The screw was illuminated by light from an arc lamp reflected from a revolving mirror attached to the screw shaft, the light falling on the screw at one point only of the revolution. The shape, form, and growth of the cavities could be clearly seen and traced as if stationary. It appeared that a cavity or blister first formed a little behind the leading edge, and near the tip of the blade ; then, as the speed of revolution was increased, it enlarged in all directions until, at a speed corresponding to that in the *Turbinia's* propeller, it had grown so as to cover a sector of the screw disc of 90°. When the speed was still further increased, the screw, as a whole, revolved in a cylindrical cavity, from one end of which the blades scraped off layers of solid water, delivering them on to the other. In this extreme case nearly the whole energy of the screw was expended in maintaining this vacuous space. It also appeared that when the cavity had grown to be a little larger

than the width of the blade, the leading edge acted like a wedge, the forward side of the edge giving negative thrust. The turbine ultimately used was of the three-stage compound order, each turbine of the series being a separate motor, though the three worked in series. Each motor actuated its own propeller shaft. The steam was expanded one-hundred-fold. The screws were 18 inches in diameter. The steam pressure in the boiler was 200 lbs., and at the engines 130 lbs. The speed of the boat was 31 knots, which is considerably in excess of any speed hitherto reached if the length of the boat be taken into consideration. The horse-power developed was 1576 as estimated, and no doubt the estimate is very close in view of the advantage Mr. Parsons has had in former trials with electrical machinery. The consumption of steam per I.H.P. per hour was 15·86 lbs., which is a remarkably good result. The indicated horse-power per ton of machinery is 72, which is, we think, in excess of anything either Mr. Yarrow or Mr. Thornycroft have attained with their destroyers, remarkable as are the advances made by these gentlemen in recent times. If, however, the boiler weights were excluded, the advantage of the *Turbinia* would be far more marked. To sum up, it may be said that Mr. Parsons has produced a very wonderful boat; but it remains to be seen how far he can maintain his success when the principle comes to be applied to vessels of a more practical character than his experimental craft. In any case, the steam turbine, in its present form, is hardly applicable to heavy and large vessels; and as yet it has not, as some have rashly asserted, revolutionised the practice of marine propulsion. What it may lead to, if the inventor can reduce the rate of revolutions in a practical and economical manner, remains to be seen. That is the great obstacle to extended success, and if it can be overcome we may expect still greater things from this new motor.

The next paper, by Mr. Ramage, was one of a purely professional interest, and as such will be of value to the ship draughtsman. Mr. Macfarlane Gray's two contributions, like all that comes from his pen, were of interest, but without the diagrams it would be difficult to deal with them. His stability diagram, we understand, is for ships' officers, and we hope that it may be of use to them. We think, perhaps, it will require a more comprehensive explanation of its principles than is given in the paper. The paper by Prof. Lewes was of a purely popular nature.

One of the most important papers was that read by Mr. Beardmore on the last day of the meeting. Its interest was of a purely practical nature, the author giving details of the properties of nickel steel as they affected engineering interests. The material is no doubt admirably fitted for construction work, having both toughness and high tensile strength; but its high price prevents it being at present, at any rate, a competitor with ordinary mild steel for ship-building, excepting in special positions, such as the construction of torpedo craft, for which it has already been used. The last paper on the list described the application of electricity for driving to certain shipyard tools, and showed how in this way advantage might be gained, in regard to coal economy, over the use of steam-driven machines.

The summer meeting this year will be held in London.

A METEORITE FROM NEW MEXICO.[1]

ON nearing Fort Stanton, Arizona Territory, while on a westward journey in 1876, Mr. M. Bartlett, of Florence, A.T., saw a meteor pass through the heavens in a southerly direction and fall, with a report like that of a cannon, on the east side of the Sacramento Mountains.

FIG. 1.—The Sacramento Mts. Meteorite. (One-eighth full size.)

The account of it was given by Mr. Bartlett to Mr. C. R. Biederman, and to the latter gentleman is due the credit of securing the specimen to science and furnishing the historical data here given.

Continued inquiry in the Pecos country was fruitless until by chance a small sample of native iron was presented to Mr. Biederman for assay, and proving to be meteoric, led to the locating of the mass through the first finder, a shepherd, named Beckett.

The latter, in a sworn statement, says that he found it while herding in the lower foot-hills of the Sacramento Mountains, Eddy Co., N.M., about twenty-three miles south-west of a place called Badger. It rested on top of a limestone hill, where it had made a depression, and was partly buried. He could find no other pieces. Mr. Biederman, heading a search party, found the mass at the place indicated, and with much labour dragged it six miles over the desert to a wagon road. A long search was made by the party, but nothing else could be found. It is complete, save for about 500 grams of fragments broken off by Beckett, and a piece of 1500 grams sawed off after it came into the possession of the firm of Dr. A. E. Foote. Its appearance indicates that no rupture occurred through an explosion during its flight, nor by the force of the fall. The small fragments mentioned were employed in analysis and the making of a knife.

Description of the mass.—It is a typical example of the class of siderites, weighing complete about two hundred and thirty-seven kilograms, with general dimensions of about 80 × 60 × 20 centimetres. The exterior exhibits in a splendid manner the characteristic markings of meteoric iron. On the flat side,

[1] Note on a new meteorite from the Sacramento Mountains, Eddy Co.' New Mexico, by Warren M. Foote. Reprinted from the *American Journal of Science* (January), with illustrations supplied by the author.

shown in Fig. 1, are two cup-shaped pits of 10 to 12 centimetres diameter, which constitute a remarkable feature; the smaller depressions or "thumb-marks" of 3 to 4 cm. diameter, which cover the remainder of the surface, are also reproduced in minute detail.

At the point where the fragments were removed, the octahedral cleavage and lines of crystallisation are noticeable to a degree rarely seen in iron. It is, however, on the etched surface—prepared through treating a polished slab with dilute nitric acid, in the usual manner—that the beauty of the crystalline structure is best seen. In this respect it ranks among the finest of recorded irons, the Widmannstätten figures being exceptionally regular and distinct. The accompanying print (Fig. 2) was made directly from the etched surface. The broad bands of kamacite are symmetrical, the prominence of the interlacing of shining white threads of the nickeliferous iron being especially remarkable, and distinguishing it from the El Capitan meteoric iron, weighing about 28 kilos, and found (Prof. E. E. Howell, *Amer. Journ. of Sci.*, vol. i. p. 253) in 1893, about ninety miles north of the Sacramento range. In the latter iron the percentage of iron is less and nickel greater, phosphorus also being present. For a careful quantitative analysis the writer is indebted to Mr. J. Edward Whitfield (with Booth, Garrett, and Blair, of Philadelphia), who obtained the following results:

Iron	91·39 per cent.
Nickel	7·86 ,,
Cobalt	·52 ,,
	99·77

The mass is perfectly preserved, there being no sign of disintegration or exudation of lawrencite. The sawing done shows it to be quite soft and generally homogeneous. The entire lack of surface alteration proves that it fell at a comparatively recent date, and leads to the conclusion that it is the meteor seen to fall by Mr. Bartlett, whose account led to the discovery.

Fig. 2.—The Sacramento Mts. Meteorite. (Printed directly from the etched surface of the iron.)

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

The University of Edinburgh has conferred the honorary degree of LL.D. upon Prof. James Dewar, F.R.S., and Dr. John Wyllie.

The following are among recent appointments:—Mr. W. J. Pope to be head of the Chemical Department of the Goldsmiths' Polytechnic Institute, New Cross; Dr. Julian Apricio to be director of the Meteorological and Astronomical Observatory of San Salvador; Dr. M. Kirchner to be professor of hygiene in the technical high school at Hanover; Dr. F. Pompeckj to be curator of the palæontological collection in the State Museum at Munich; Dr. F. Koch to be professor of chemistry at Klausenberg.

The Technical Education Board of the London County Council has decided to institute junior horticultural scholarships tenable at the gardens of the Royal Botanic Society. These scholarships are intended to offer to boys who wish to become gardeners an opportunity of going through a thorough course of training, and they will be awarded, not upon the results of a set examination, but upon a consideration of the record and qualifications of the candidates. Free instruction in horticulture will be provided, with a maintenance grant of 20*l.* per annum to scholars under fifteen and 25*l.* to scholars over fifteen. The scholarships will be awarded, in the first instance, for one year, but will be renewable for a second, or even for a third year, if the progress of the scholar is satisfactory. No candidate will be eligible for these scholarships whose parents are in receipt of more than 250*l.* per annum.

By an Act passed in 1889, a Commission was appointed for organising and extending the scope and teaching power of the departments of the Scotch Universities, and the effect of the Commissioners' ordinances on the University of Aberdeen was to add a new faculty—that of science—as well as to expand the four former faculties, and largely to increase the building requirements in respect of laboratories, museums, &c., in almost all the departments of the University, while it made no provision for supplying the buildings to accommodate them. The University was, in these circumstances, compelled to build, but had no funds for the purpose. In 1892 Mr. Goschen, then Chancellor of the Exchequer, agreed to give a grant of 40,000*l.* if the public subscribed a similar sum. An appeal was made, and 75,000*l.* were raised, which, with the Government grant, gave a total of 115,000*l.* This amount has been expended, while the works at present in progress entail a further liability upon the University of fully 21,000*l.* To meet this exigency, as well as to complete the buildings extension scheme, and the still urgent necessities of the University, a total sum of at least 40,000*l.* is required; and an urgent appeal has been sent out in the hope that those who are interested in this historic University will assist in the extension of its usefulness. Subscriptions will be received by the honorary secretaries of the Extension Fund: Mr. A. M. Gordon, of Newton, Convener of the County of Aberdeen; and Mr. P. M. Cran, City Chamberlain, Aberdeen.

The value of science as an instrument of education is now recognised by all educationists who have taken the trouble to consider the matter; but we hasten to say that the scientific knowledge must be gained by individual experience with the objects and phenomena of nature. This principle is so sound that its application is bound to extend. For some years experimental work in elementary science, on the lines suggested by Dr. H. E. Armstrong, has been carried on with great success in about fifteen selected schools under the London School Board. The results have been so satisfactory, that it has been felt that girls as well as boys ought to be given the same training in manipulation and common sense; and to further such an object, a meeting of about two hundred teachers took place on Saturday, April 3. The following resolutions formed the basis of discussion, and were carried *nem. con.*: (1) That there is great room for improvement in the methods of teaching domestic economy as commonly practised in schools, and it is desirable that in

future the teaching should be of a more exact nature, and such as to make the scholars think for themselves about the ordinary affairs of the household. (2) That the time is arrived when it is absolutely necessary to introduce into girls' schools of all grades, and from the outset of the school course, simple but accurate experimental work dealing with domestic matters. (3) That the meeting notes with satisfaction the introduction into the Code of the Education Department of the new subject domestic science as tending to the promotion of the changes suggested in the two preceding resolutions.

A LONG article by Sir Philip Magnus, in the April number of the *National Review*, carries on the crusade in favour of an improved organisation of scientific education and opinion as a means to industrial progress. He does not counsel slavish imitation of German methods, but shows that the advance of German manufacturing industry is largely due to a full and generous recognition of the great part played by science in national progress. It is instructive to compare Germany and England by means of sentences taken from different parts of Sir Philip Magnus' article.

Germany.	*England.*
The recognition of the advantages of scientific and technical education characterises all classes of society in Germany, and none more than employers of labour engaged in productive and engineering industry.	Unfortunately, there is considerable doubt among certain classes of manufacturers, and even among engineers, as to the value of education in assisting industry; and, judging from the treatment in Parliament of all educational measures, it would seem that our legislators are still unconvinced of the economic importance of the subject.
Between the elementary school and the technical high school or university there is an intelligible and well-coordinated system, which gives unity to the entire system of education.	At present our schools are only *disjuncta membra* of what we hope may one day become a system.
Care is taken that the influence of the Minister of Instruction, and of those who advise him, shall penetrate into every small rural School Board.	There is no responsible authority to supervise or grade our several educational institutions, so as to bring them into organic relation with one another.

General Conclusions.—German education is superior to our own in its appliances (schools and their equipment), methods of instruction, and organisation. The instruction is also more closely adapted to the wants and requirements of the people.

SCIENTIFIC SERIALS.

Bulletin of the American Mathematical Society, March.—On certain methods of Sturm, and their application to the roots of Bessel's functions, by Prof. M. Böcher. This is a paper read before the Society at its February meeting, of which the purpose is to call attention to Sturm's methods, rather than to elaborate the details of the theory of the roots of Bessel's functions. These methods, which appear to have been overlooked, are given by Sturm in *Liouville's Journal*, vol. i. p. 136, &c. In addition to the Professor's own work, the paper discusses two recent proofs of theorems, really contained in Sturm's article, given by Messrs. Porter (a graduate student at Harvard) and Van Vleck (*American Journal of Mathematics*, xix. p. 75).—Dr. G. A. Miller, in a paper read at the January meeting, continues his work on groups. The article is on the transitive substitution groups, whose orders are the products of three prime numbers.—Note on the integration of a uniformly convergent series through an infinite interval, by Prof. T. S. Fiske, was also read at the same meeting. It illustrates a communication by Prof. Osgood, which was published in the November number of the *Bulletin*.—Short notices follow, by Prof. F. Morley, of Dr. L. Huebner's "Ebene und Räumliche Geometrie des Masses," and, by Prof. E. W. Brown, of the scientific papers of John Couch Adams.—Some points of interest are brought forward in the usual notes.

IN the numbers of the *Journal of Botany* for February, March, and April, Messrs. W. and G. S. West continue their description of the Fresh-water Algæ collected by Welwitsch in Africa, comparatively new ground; a large number of new and beautiful forms, and several new genera, being described and delineated. Mr. I. H. Burrill commences an elaborate article on the fertilisation of spring flowers on the Yorkshire coast, containing the results of a long series of careful observations, the general conclusions from which will appear in a later number.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, March 11.—"The Comparative Physiology of the Suprarenal Capsules." By Swale Vincent, M.B. (Lond.), British Medical Association Research Scholar. Received February 18.

The conclusions arrived at are as follows:—

(1) The suprarenal capsule of the mammalia corresponds to two distinct glands in Elasmobranch fishes, the medulla corresponding *in structure and function* to the "paired segmental" suprarenal bodies ("medullary glands" they may be called), while the cortex corresponds to the interrenal body.

(2) In Teleosts the medulla appears to be unrepresented, the known suprarenal bodies ("corpuscles of Stannius") consisting entirely of cortical substance, and corresponding in structure, and most probably in function, to the interrenal body of Elasmobranchs.

(3) The same is most probably true of Ganoids, although I am guided here solely by histological evidence; I have not been able to obtain sufficient and suitable material for physiological investigation.

Thus it appears from these researches that two primary groups of the class *Pisces* (Teleosts and Ganoids) have no "medulla" but only "cortex." So far as I know, the only piece of work published on the physiology of the suprarenal capsules in fishes is that of Pettit (12). This observer has made out a true physiological compensatory hypertrophy of one suprarenal in the eel after the other one has been removed. This renders it probable (what indeed was suggested by histological appearances) that this "cortical gland" has a secreting function. Pettit looks upon this organ in the eel as the fundamental type of the suprarenal capsule, but it appears to me much more probable that it represents cortex alone.

Physical Society, April 9.—Mr. Shelford Bidwell in the chair.—Mr. T. A. Garrett read a paper on a nickel stress telephone. In conjunction with Mr. W. Lucas, the author has experimented upon telephones with nickel magnets. A magnetised nickel rod is wound with insulated wire, and is then fixed vertically by a clamp at its lower end. A wooden diaphragm is rigidly attached to the top of the rod in a horizontal plane. The rod just passes through the middle of the diaphragm, where it is fixed with sealing-wax. The diaphragm is entirely supported by the nickel rod. On speaking against the top of the diaphragm, variations of longitudinal pressure, and consequently of magnetisation, are produced in the nickel, and corresponding undulatory currents are induced in the surrounding coil. The nickel wire is sometimes magnetised by stroking it with a magnet, and sometimes by passing a current through the coil. A diaphragm of pine-wood gives better results than a metallic plate. The instrument does not work well as a "receiver"; an ordinary telephone is used for this latter purpose. The results obtained with a weakly-magnetised nickel rod are much better than those with a strongly-magnetised steel rod, indicating that the undulatory currents are due rather to magnetic variations arising from changes of stress than to the relative motions of the magnet and coil. Dr. S. P. Thompson said that, some years ago, he had worked with a somewhat similar apparatus, using it as a "receiver," with wires of nickel, cobalt, and iron. Cobalt gave the best results; the metallic strips in his experiments dipped into the solenoids without contact with them. This arrangement did not work well as a "transmitter," even when a battery was included in the circuit. In some cases the rods were cut into short lengths separated by brass. Mr. Boys asked how the nickel "stress" instrument compared in clearness and loudness with an ordinary telephone. Mr. Shelford Bidwell had tried a nickel telephone

with a mica diaphragm, depending not upon mechanical stress, but magnetic strain. It did not work well. Dr. Chree thought the "stress" telephone might possibly be improved by choosing the right strength of magnetic field. Mr. Appleyard said the arrangement was interesting historically, because it was, mechanically, almost identical with the original instrument used by Philip Reis as a "receiver." The authors had succeeded in getting it to work as a "transmitter." Their success was probably due to the rapidity with which the magnetisation of nickel responded to very small changes of stress or current. The Post Office electricians had tried to introduce nickel cores into relays, on account of its magnetic sensitiveness; the results, he believed, had not been very satisfactory. Mr. T. A. Garrett, in replying, said the "stress" telephone gave better articulation than an ordinary "watch" telephone, but the sounds were feebler. There seemed to be a field-strength proper to the instrument: he had noticed that the articulation was clearer with three cells than with six.—Mr. W. A. Price then read a paper on alternating currents in concentric conductors. This is a mathematical investigation of a proposed new form of submarine cable. The case is considered of two concentric conductors, interrupted alternately at different points throughout the whole length. In the mathematical treatment, the cable is supposed to be laid in a circular path, and successive charges of electricity are supposed to be applied at some point at the extremity of a diameter of the circle. Expressions are given for the amplitude of the periodic charges arriving at a point diametrically opposite to the first; and for the reduction in amplitude, throughout the whole length of the cable, of an applied E.M.F. The theory indicates that under no circumstances can the "speed" of a cable of the proposed form be greater than the "speed" of a cable of ordinary type. The author has experimented upon an artificial cable connected up to represent the proposed form. The "definition" of signals is considerably better than that obtained through an artificial cable of analogous "weight" and "length" connected up in the ordinary way. Within certain limits the "definition" continues to improve as the number of sections, or subdivisions, of the cable is increased.—Mr. Blakesley said he was sorry the result did not indicate a successful type of cable. He would have been inclined to predict that the amplitude would have decreased with the number of sections. If a number of condensers were joined in series, and one end was subjected to a periodic E.M.F., the amplitude would fall off inversely as the square of the distance. Mr. Price then exhibited a galvanometer support. The instrument was suspended from two india-rubber cords, attached at the top and bottom to cross-bars of metal, thus forming a rectangle. The cross-bars were provided with knife-edges in such a way as to compensate for unequal stretching of the india-rubber. Weights could be added, if necessary, to the support, so as to increase its inertia.—Mr. H. Garrett read a paper, communicated by Prof. W. B. Morton, on the effect of capacity on stationary electrical waves in wires. The author investigates the effect produced when a condenser is inserted at a point in the secondary circuit of the apparatus used by Blondlot for obtaining stationary electrical waves in wires. The positions of successive nodes are determined in the usual way, by a bridge, with a vacuum-tube indicator. When two opposite points of the parallel secondary wires are joined to the plates of a small air-condenser, the nodes approach the condenser on either side. The amount of the displacement of the nodes—that is to say, the extent of the shortening of the apparent half-wave-length—depends upon the position of the capacity along the wire. The effect is *nil* when the condenser is at a node, and a maximum when it is midway between two nodes. The state of affairs at a point of the circuit is obtained by summation of a series of separate disturbances due to the different direct and reflected trains. In obtaining a formula for the conditions of resonance, with which to compare the observations, the author adopts a method from Heaviside. It connects the frequency of oscillation, with the position and capacity of the condenser.—Mr. Shelford Bidwell proposed a vote of thanks to all the authors, and the meeting was adjourned until May 14.

Zoological Society, April 6.—Dr. W. T. Blanford, F.R.S., Vice-President, in the chair.—The Secretary exhibited, on behalf of Mr. A. J. Lawford Jones, a curious cinnamon-coloured variety of the blackbird (*Turdus merula*), which had been captured near Dorking, Surrey.—Prof. B. C. A. Windle and Mr. F. G. Parsons contributed the first part of a paper "On the Myology of the Terrestrial Carnivora," which dealt with the muscles of the head, neck, and fore-limb of eighty-three individuals.—A communication was read from Mr. C. S. Tomes, F.R.S., on the minute structure of the teeth of *Notoryctes*. An examination of its dentition had confirmed the view previously arrived at by other naturalists that this animal has affinities with the *Dasyuridæ* and *Didelphidæ*.—A communication was read from Mr. R. Lydekker, F.R.S., entitled "The Blue Bear of Tibet, with Notes on the Members of the *Ursus arctus* Group." The author described a mounted specimen in the British Museum, which he identified with the *Ursus pruinosus* of Blyth. He also made a survey of the other members of the *U. arctus* group, and came to the conclusion that, with the exception of the extinct *U. spelæus*, they should all be regarded as subspecies rather than species. As they are all structurally similar, they seem, in his opinion, to be merely local varieties and colour-phases of what is essentially one animal.—Mr. G. A. Boulenger, F.R.S., gave an account of the fresh-water fishes collected in Celebes by Drs. P. and F. Sarasin. The specimens obtained were referred to fourteen species, of which four were described as new, one of them forming the type of a new genus of *Atherinidæ*, proposed to be named *Telmatherina*.

Edinburgh.

Mathematical Society, April 7.—Dr. Sprague, President, in the chair.—The following papers were read: (1) Certain expansions of x^n in hypergeometric series, Rev. F. H. Jackson; (2) the C. discriminant as an envelope, Mr. Jas. A. Macdonald; (3) the factorisation of $1-2x^n\cos\alpha+x^{2n}$, Prof. John Jack.

Paris.

Academy of Sciences, April 5.—M. A. Chatin in the chair.—Periodic solutions and the principle of least action, by M. H. Poincaré.—Preparation of iron carbide by direct union of metal and carbon, by M. Henri Moissan (see p. 566).—On the Innucellæ or Santalineæ, a subdivision of the Inseminæ, by M. Ph. van Tieghem. The entire group of the Santalineæ comprises fifteen genera, the distinguishing characteristics of which are given.—M. Radau was elected a member in the Section of Astronomy, in the place of the late M. Tisserand.—The Commissions were elected for judging the memoirs sent in for the Godard, Parkin, Barbier, Lallemand, Larrey, Bellion, Mège, Montyon (Experimental Physiology), La Caze (Physiology), and Martin-Damourette prizes for 1897.—On the accidents which may be produced by heating with hot air, by M. N. Gréhant. In several cases of accidents attributable to emanations from heated iron pipes, the air of the room was carefully examined for carbon monoxide. In nine cases out of ten, however, the results obtained were negative, carbon monoxide being clearly present (·04 per cent.) in one case only. Further experiments were then carried out to see whether the method of analysis adopted could detect the passage of carbon monoxide through the walls of an iron stove kept at a dull red heat. The presence of CO was clear, although the air collected contained only ·015 per cent. of the gas.—On a clockwork myodynamometer, by the same.—The drawings on the rocks of the La Mouthe Cave (Dordogne), by M. É. Rivière. The antiquity of the drawings is proved by the fact that they are in part covered by the clay which constitutes the floor of the cave. This clay contains the remains of several species of animals, all quaternary. Three of the drawings were of animals, one of which is undoubtedly a bison (*Bos priscus*). Another drawing represents a kind of hut. Other drawings have been partly exposed, the excavation of which is being proceeded with.—Letter addressed to M. Berthelot by Mr. H. Wilde, F.R.S., concerning the offer of 5500*l.* to be applied to founding an annual prize for a work on Astronomy, Physics, Chemistry, Mineralogy, Geology, or Mechanics.—On mechanical quadratures, by M. B. Baillaud.—On the general theory of surfaces, by M. A. Pellet.—On the deformation of certain paraboloids, and on the theorem of M. Weingarten, by M. Eugène Cosserat.—On linear partial differential equations of the second order with two variables, by M. Cotton.—On the properties of complete functions, by M. Desaint.—On the partial polarisation of radiations emitted by some luminous sources under the influence of the magnetic field, by MM. N. Egoroff and N. Georgiewsky. The results of M. Zeeman on the polarisation of rays from luminous flames by the action of a strong magnetic field were confirmed and enlarged, as, without the use of a spectroscope, the partial rectilinear

polarisation of the rays from lithium, sodium, and potassium flames, and also the rays from sparks between magnesium electrodes, was proved. Sparks between electrodes of carbon, aluminium, mercury, zinc, bismuth, and iron showed no trace of polarisation with the same Savart analyser.—New cadmium lamp for the production of interference fringes, by M. Maurice Hamy. An improvement on the cadmium tubes used by Michelson in his determinations of the relations between the wave-lengths of light and the metre. No electrodes are carried through the glass, the ends being enclosed by brass caps with graphite packing, and the tube in use being kept at about 350°. The tubes will stand over twenty hours' use without losing any of their brilliancy.—Researches on nickel steels: metrological properties, by M. C. E. Guillaume. The remarkable property of some nickel steels of having a coefficient of expansion nearly equal to zero, naturally suggested the use of these alloys in the construction of measuring instruments. With a view of seeing how far their mechanical properties are suitable, a series of alloys containing from 5 to 45 per cent. of nickel was studied as regards densities and elastic properties.—On the nature of the several species of radiations produced by bodies under the influence of light, by M. Gustave Le Bon.—An induction oscillograph, by M. H. Abraham.—On the variation of the electric state of high regions of the atmosphere in fine weather, by M. G. Le Cadet. The electric field is weaker at altitudes above 1500 metres than on the surface of the earth.—On a new oxide of phosphorus, by M. A. Besson. Although PH_3 does not react upon pure $POCl_3$ at any temperature below the boiling-point of the latter, a reaction takes place if a little HBr is also present with the formation of a lower oxide of phosphorus, apparently P_2O. The same substance is obtained by heating $POCl_3$ and PH_4Br together in a sealed tube at 50°. The new oxide forms a yellowish-red powder, not changed by heating to 100°. The formula was deduced from the analysis of the powder, no evidence being produced, however, to show that this consists of one oxide only.—On metastannyl chloride, by M. R. Engel.—The action of a high temperature upon the sulphides of copper, bismuth, silver, tin, nickel, and cobalt, by M. A. Mourlot. At the temperature of the electric furnace, cupric sulphide is reduced to cuprous sulphide and metallic copper, bismuth and silver sulphides to the metals, tin sulphide to the stannous salt, nickel sulphide to a sub-sulphide Ni_2S. Cobalt sulphide does not give a corresponding salt.—Combinations of ammonia gas and methylamine with the haloid salts of lithium, by M. J. Bonnefoi.—Action of gallic and tannic acids upon some alkaloids, by M. Oechsner de Coninck.—Preparation of sodium carbide and sodium acetylide in the pure state, by M. Camille Matignon.—Observations concerning the temperature of freezing of milk, by M. J. Winter. A reply to MM. Bordas and Génin.—On the non-identity of lipases of different origins, by M. Hanriot.—Two preparations of lipase, the one from blood serum, the other from the pancreas of the dog, showed marked differences in their saponifying action upon butyrin under similar conditions.—Some properties of the ferment causing the decolorisation of wines, by M. P. Cazeneuve. It has been previously shown that the cause of decolorisation of wine (*la casse*) is an oxidising ferment, the action of which is completely prevented by the addition of a small quantity of sulphurous acid to the wine. In the present communication the action of this sulphurous acid is shown to be due to a specific action upon the oxydase, and not merely to its reducing action, since a much larger amount of formaldehyde did not prevent decolorisation.—On a new method of obtaining the essential perfume of flowers, by M. Jacques Passy.—Researches on the development of the archegonium in the Muscineæ, by M. L. A. Gayot.—The law of formation of the transversal valleys in the Eastern Alps, by M. Maurice Lugeon.—The influence of franklinisation upon the singing voice, by MM. A. Moutier and Granier.—The action of currents of high frequency upon the virulence of the streptococcus, by M. Louis Dubois. Cultures of streptococcus showed a marked diminution in virulence after being repeatedly exposed to the effects of a high frequency current.—Action of the X-rays upon the heart, by MM. Gaston Seguy and F. Quénisset. Prolonged exposure to the X-rays has in several cases caused violent and irregular palpitation of the heart.—On the actinomycosic form of the tuberculosis bacillus, by M. M. V. Babes and C. Levaditi.—Note on the grouping of the stars, by M. Delauney.—On an improvement for the production of acetylene from calcium carbide, by M. Lechappe.

DIARY OF SOCIETIES.

RELIGIOUS SUPERSTITIONS OF NORTHERN INDIA.

The Popular Religion and Folk-Lore of Northern India. By W. Crooke, B.A. Two volumes. Vol. i. pp. 294; vol. ii. pp. 359. (Westminster: Archibald Constable and Co., 1896.)

THESE two volumes are a reproduction, on a larger scale, of a work written in 1894, by Mr. W. Crooke, of the Bengal Civil Service. The author employed the interval, so he tells us, in collecting fresh information in the course of the Ethnographical Survey of the North-west Provinces of India, the results of which will be separately published. This new edition contains a mass of most important and extremely interesting matter, ably dealt with by a thoroughly competent authority, in whom are combined the rare qualities of careful and accurate research with an intimate knowledge of the habits and customs of the people of Northern India. The value of the work is further enhanced by excellently executed photographs of shrines and other sacred places, a complete bibliography, and a carefully-prepared index.

The first volume deals chiefly with the "godlings," or inferior deities commonly worshipped by the masses, which are distinct from the high gods described in the Vedic hymns, and the Triad, or Trinity, whose attributes are set forth in the Purânas and other sacred works of the Brâhmans. The reader is no doubt aware that the earlier and more philosophic forms of Hinduism are not now, if they ever were, the religion of the people. The older creed is buried under an enormous overgrowth of demonolatry, fetishism and kindred forms of primitive religion, not described in books, nor patronised by high-caste priests, but living in oral traditions, and forming the daily cult of almost all classes of society in modern India. It is this form of Hinduism, and the folk-tales and customs associated with it, that the author has brought to light and placed before the English reader. Religion, as the author shows, went through the same phases of growth in Christian Greece and Rome that Hinduism has undergone in India.

The popular deities of modern India are described under five main headings—the godlings of nature, the heroic and village godlings, the godlings of disease, the sainted dead, and the malevolent dead. To illustrate each of these subjects the author has taken examples not only from those castes which call themselves Hindu, but also from those tribes which it is convenient to describe as aboriginal, or non-Aryan, and which have not yet been drawn within the vortex of Hinduism. Among the godlings of nature the author includes the Sun (Suraj Narâyan), the Moon (Chandra or Sama), the demon of the moon's eclipse (Râhu), the rainbow, the Milky Way (known to some as the pathway of the snake, to others as the course of the heavenly Ganges), mother earth, thunder and lightning, the sacred junctions of rivers, sacred wells and lakes, hot springs, waterfalls, sacred mountains, hail and whirlwind, aerolites, &c. Among all those godlings of nature some stand higher in the list of benevolent deities than the great rivers, especially the Ganges and the Jumnâ. The Ganges, known as Gangâ Mâi, or "Mother Ganges," in the mythologies has a divine origin. According to one account she flows from the toe of Vishnu, and was brought down from heaven by the incantations of the saint Bhâgiratha, to purify the ashes of the 60,000 sons of King Sâgara, who had been burnt up by the angry glance of Kapila, the sage. By another story, she descends in seven streams from Siva's brow, and by a third account she is the daughter of Himâvat, the impersonation of the Himalayan range.

The heroic village godlings make a numerous class; and Muhammadans, in spite of their professions of rigid orthodoxy, have sainted heroes, to whom they make offerings and prayers, no less than Hindus. In fact, the same hero is often worshipped by the followers of both creeds. Of this there are two notable examples. One is Khwâja Khizr, a saint of Islâm, who presided over the well of immortality, and directed Alexander of Macedon in his vain search for the blessed waters. The fish is his vehicle, and hence the emblem of a fish became the family crest of the late royal house of Oudh. Out of this Muhammadan saint the Hindus have evolved a water-god, to whom they have given the name of Râja Kidar, by a process of change from Khwâja Khizr. In this capacity he has become the patron deity of all the boating and fishing castes, Hindu and Muhammadan. The other example is that of Ghâzi Miyân, whose shrine is situated at Bahraich, in the north of Oudh. "His real name," says the author, in page 207, "was Sayyid Sâlâr Masaud, and he was nephew of Sultân Mahmûd of Ghazni." It would have been more correct, however, if he had said that his real name is Shahîd (or "Martyr") Masaud, which was corrupted in popular ignorance to Sayyid, or descendant of the prophet. Sultân Mahmûd did not profess to be a Sayyid; and his nephew Sâlâr received the title of "Shahîd," or Martyr, from the fact that in A.D. 1033 he was killed in battle by the Hindus of Bahraich. Mr. Crooke suggests the following hypothesis in explanation of the fact that his shrine is worshipped by Hindus, to whom he was a bitter enemy, no less keenly than by Muhammadans.

"There is some reason to believe that this cultus of Masaud may have merely succeeded to some local worship, such as that of the sun, and in this connection it is significant that the great rite in honour of the martyr is called the Byâh or marriage of the saint, and this would associate it with other emblematical marriages of the earth, and sun or sky, which were intended to promote fertility. Masaud, again, is the type of youth and valour in military Islâm, and to the Hindu mind assumes the form of one of those godlike youths, such as Krishna or Dûlha Deo, snatched away by an untimely and tragical fate in the prime of boyish beauty."

It says much for Mr. Crooke's penetration that the hypothesis he has suggested is verified by the family records of a neighbouring Hindu Râja. What is now known as the shrine of Sayyid Sâlâr was originally the temple of the Infant Sun, worshipped under the name of Bâla Arka ("the rising sun"). It was near this spot that the filibuster was slain and buried. Amongst Hindus the propensity to hero-worship is so strong that veneration for the sun-godling was gradually absorbed in tha

of the deified Muhammadan saint, whom their ancestors had slain. All through the year pilgrims frequent this shrine, but the special anniversary of his worship occurs in the month of May, one of the hottest months of the year, when the crush of pilgrims struggling to leave some offering at the tomb is so great that the consequences are sometimes fatal. A thermantidote was fixed a few years ago at the back of the tomb, to supply a current of cool fresh air to persons entering in at the front. This the pilgrims declare is the holy breath of the saint breathing on them; and they go round to the back of the tomb and pay worship to this thermantidote.

The godlings of disease are described in full detail in Chapter iii. Most of these are goddesses, various forms of Kâlî, the goddess of death. The most conspicuous are Sîtalâ, the goddess of small-pox; and Marî Bhavânî, the goddess of cholera. The latter shares her honours with another form of the cholera godling, who is a male, and is called Hardaul Lâla. He is chiefly worshipped north of the Jumnâ. It is noticeable that there is no godling to represent the plague that is now raging in the Bombay Presidency, implying, what is the fact, that this fell disease has never before been known in India. If it should become an endemic it will no doubt be personified, and another godling will then be added to the already overcrowded panthcon.

The reader will find much to interest him in the second volume, but we have no space to go into details. In pp. 13–14, he will find some curious facts about the use of a horse-shoe for securing good luck, and warding off the evil eye. The custom of nailing against a door horse-shoes that have been accidentally picked up is as common in India as in England: "the great gate of the mosque at Fatehpur Sikri is covered with them, and the practice is general at many shrines." It is interesting also to find that customs similar to that of throwing rice at a bride as she leaves the church are widely prevalent in India.

Mr. Crooke devotes several pages to the subject of human sacrifice (vol. ii. pp. 167–176). There is no reason to doubt that this custom prevailed among the early Aryans of India. The Tantras enjoin human sacrifices to Chandikâ. The folk-tales of India abound in stories of human sacrifice; and in the time of Sir John Malcolm there was a tribe of Brâhmans called Karhâda, which had a custom of annually sacrificing a young Brâhman to their deities. All over India there is a very strong tradition that new buildings, bridges, tanks, and wells should be secured against evil by the blood of some human victim.

The reader of these fascinating volumes cannot fail to be deeply interested in their perusal; he will also realise what a wide field of research is open to the methodical and careful observer of Indian modes of life, of their religious beliefs and superstitions. It is extremely creditable to Mr. Crooke that such a valuable work should have been compiled in the intervals of the scanty leisure of a District Officer's life in India. It is to be hoped that officials in other provinces of that vast empire, with its countless tongues, races and tribes, may be induced to follow in Mr. Crooke's worthy footsteps.

It is a matter of considerable surprise that the Government of India, instead of establishing an ethnological bureau whose entire work shall consist in collecting the traditions and customs of the people in each of the various provinces, should have allowed private individuals, already overburdened with work, to carry on such important researches at their own cost, and in the short intervals of hard-earned leisure. In this connection we would allude to the labours of Mr. Denzil Ibbetson, the author of "Panjâb Ethnography"; to Colonel Dalton's "Ethnology of India"; to the important summary on the caste-system of the North-west Provinces and Oudh, monographs on the Kanjar, Mushera, Thâru, and other tribes, with sundry ethnographical treatises written by Mr. J. C. Nesfield; to Mr. Risley's "Tribes and Castes of Bengal"; to Mr. Eustace Kitt's "Compendium of Castes"; and to other similar works by eminent Indian officials, who have so largely contributed to the literature relating to the folk-lore, traditions, and religious beliefs of the people of India.

PRIMITIVE MAN IN EGYPT.

Recherches sur les Origines de l'Égypte. L'Âge de la pierre et les Metaux. Par J. de Morgan. Pp. xiv + 270, large 8vo. (Paris: Leroux, 1896.)

THE excavations which have been carried on in Egypt during the last twenty years have had as their object the acquisition of antiquities rather than the scientific investigation of the numerous problems anent the early Egyptians and their predecessors, which still, unfortunately, remain unsolved. It cannot be denied that public interest in the work depended largely upon the value of the facts which could be deduced from the study of Egyptian antiquities in their relation to the history of the sojourning of the children of Israel in Egypt, and it is only quite lately that attempts have been made to treat the various branches of Egyptology from a comparative point of view. Moreover, a mistaken idea had gone abroad about the ability of the Egyptologist to settle the difficulties which constantly cropped up, and the philologist was thought to be able to give a final answer to every question which was propounded to him.

It is now quite clear that the knowledge of the Egyptians is a subject sufficiently large to admit of the useful occupation of purely scientific men in addition to the philologist; and the sooner this fact is generally recognised the sooner we may hope that fresh light will be thrown upon the dark and somewhat mysterious past of the early Egyptians. A limit must be reached some day in philological knowledge of Egyptian archæology, and our hope for further facts must rest upon those who are able to put before us the interpretation of the story of Egypt's past, which is written in her mountains and mud.

It will be remembered that the labours of Mariette and Maspero were devoted entirely to the collecting of antiquities, and to the publication of texts and papyri, and to the general administration of the Egyptian Museum of Bûlâk and Ghîzeh. Their successor, however, M. J. de Morgan, has approached the duties of his post with a larger view of their possibilities, and he has devoted himself to the consideration of the ancient country of Egypt rather than to its language. The results of his excavations have, notwithstanding, been important, and the jewellery of Dahshûr will for long claim the attention of all lovers

of art and of all admirers of technical skill in the working of metals.

It is our purpose not to discuss these results, but to draw attention to his geological investigations which he describes in the work before us, for here we have presented a series of facts which have been brought together by a trained observer of physical phenomena, and a number of deductions which claim the careful thought of those who deal with the science of anthropology.

By the aid of "black and white" maps, we have a brief account of the early geological changes which took place in Western Asia and resulted in the formation of Egypt, and the old course of the Nile now called "the river without water," and its relation to the bases are fully described; this is followed by an account of the gradual development of the Nile as we know it, and the causes which produced the fertile lands on each side of it. The first peoples who lived on the latter were the autochthonoi, who perfected the art of stone polishing: who became almost civilised, and who were known by the historical Egyptians as the "followers of Horus"; these M. de Morgan divides into two classes, *i.e.* palæolithic and neolithic. Of palæolithic man many remains have been found, and four places, at least, where it is certain that he flourished are now well known, and many examples of his stone work are figured on pp. 57-66 of M. de Morgan's book.

Passing next to the remains of neolithic man, we find that numerous sites, both in Lower and Upper Egypt, produce objects which prove his skill and knowledge; these are here described with care, and the deductions which are to be made from the objects on each are soberly stated.

Without going into details, M. de Morgan proves with tolerable certainty that we have authentic remains of the historic Egyptians of the first and second dynasties, and there are many objects known to him which he would attribute unhesitatingly to the period immediately preceding. Here, naturally, comes an account of M. Amélineau's discoveries, which have stirred up a great deal both of interest and strife, and a statement of the excavator's own views on the subject has been given from his paper entitled *Les Nouvelles fouilles d'Abydos*, Angers, 1896. Whether the objects found in the tombs at Amrah, near Abydos, belong to as early a period as M. Amélineau asserts; or whether they come from what M. de Morgan calls "tombes de transition," and are to be attributed to the kings of the autochthonoi of the time of the first and second dynasties; or whether they belong to a much later period, as Brugsch Bey, Maspero and Petrie declare, cannot be decided off-hand; but there is no doubt whatever that they are exceedingly ancient, and that they form a sort of half-way stage between the antiquities of the sixth dynasty and those of the period somewhat anterior to the reign of Menes. At all events, they form a factor which must be reckoned with, and they are not to be lightly pooh-poohed without careful study; we agree with M. de Morgan that they are of royal origin, and that they indicate a transition period when both polished stone and metals were used as materials for weapons.

Following these considerations, M. de Morgan shows by a figure how the skeleton, vases, &c., were arranged in the tombs of Amrah, and some hundreds of drawings illustrate the flints and other objects found therein. The painted vases are, naturally, the antiquities to which the attention of most readers will be drawn, and it seems tolerably certain that few archæologists in the present state of the case will agree in their deduction as to date and period. With the advent of the historical Egyptian, neolithic man disappeared in Egypt, and then came into being the monuments which have long excited the wonder and admiration of the whole civilised world.

But where did this Egyptian come from? M. de Morgan agrees with many in thinking that he came from Asia, and he looks upon Chaldea or Southern Babylonia as his probable home; but many will be surprised to learn that the *fellah*, or peasant countryman, whom many experts have regarded as the lineal descendant of the Egyptian who built the pyramids and temples, is the product of the mingling of the autochthonoi with Nubians and Egyptians. In an "Appendix" Dr. Fouquet, the famous craniologist, gives the results of his examination of nineteen boxes of bones from Amrah, and, though asking his readers to suspend their judgment for the moment, he seems to be on the whole inclined to believe generally in the great antiquity assigned to the tombs and their owners by MM. de Morgan and Amélineau. M. de Morgan's book bristles with interesting points, but many are unfortunately debateable, and there can be no doubt that some of his views will be rejected by his fellow-workers. The value of his book consists not only in the newness of the facts which he produces, but also in the carefulness of his arrangements of them and the deductions therefrom; and something is to be said for the honesty which he displays in discussing subjects with which he is well acquainted, and in leaving those of which he has no special knowledge to the investigations of experts.

OUR BOOK SHELF.

Magnetic Fields of Force. By Prof. H. Ebert. Translated by Dr. C. V. Burton. Part i. Pp. xviii + 297. (London: Longmans, 1897.)

The author's preface points out the advantage of investigating the different phenomena of magnetism from the conceptions of Faraday, which were further developed by Maxwell and Helmholtz. Special prominence is given to the principle of the lines of force, the field as being the seat of the energy, and the symmetry of the field.

Part i. is intended as an introduction to the subject, and is quite elementary. The book is divided into two sections, of which the first treats of the phenomena of magnetism, and the second of the phenomena of the galvanic current and electro-magnetism.

The first section deals with the properties of artificial magnets, and describes several easy experiments which illustrate clearly the various principles. It also contains much general information on the magnetic effects which are met with in nature. In contrast to the rest of the book, there are a few places where the explanations are very confusing. Thus, on page 131, the following definition is given of magnetic induction:—"The magnetic condition is determined by the number of lines of force per unit of cross sectional area, the important magnitude thus measured being called the magnetic induction. In order to arrive at the equation $B = 4\pi I + H$ the usual method of cutting a gap in a uniformly

magnetised toroid is adopted, and then the following statement is made. "Then in accordance with § 99 there will be $4\pi I$ lines of force passing across each square centimetre of the gap, and these continue their course to the same number through the substance of the toroid." The latter part of this statement is wrong if we allow that the force at every point of the field can be calculated from the law of inverse square, for the surface distribution of magnetism on the opposite faces of the gap is + and − I; so that if the gap is narrow the force in the gap is $4\pi I$, but is zero at every other part of the field, including the substance of the toroid itself. Apart from this, the book itself contains a statement which directly contradicts the idea of there being any force inside a uniformly magnetised toroid, for on page 120 the following sentence occurs. "Since such a toroid neither emits nor absorbs lines of force, it is without magnetic influence. In its interior also it may be shown that its magnetic force vanishes."

The second section contains a full account of the elementary properties of the electro-magnetic field of force. The diagrams showing the directions of the lines of force in the various cases are especially instructive, and are arranged in a manner that would assist the student to form a mental picture of the position of the lines of force for simple conductors.

Questions involving mathematics are avoided throughout the whole book, so that it would be ill-suited for a student who could arrive at all the results by the application of simple mathematics. There is, unfortunately, a large number of students who learn physics without having a mathematical training, and they will no doubt find in Part i. much useful information, and experimental proofs of the various properties of magnetic forces due to magnets or electric currents.

A list of errata would have been useful, as there are a few misprints, as on pages 81 and 86, in the dimensions of the units.

Part i. only contains the elementary theories; but in Part ii. the author intends to treat of the more advanced branches of the subject which come under the head of induction and electrical oscillations. J. S. T.

A Study of the Sky. By Herbert A. Howe. Pp. xii + 335. (London: Macmillan and Co., Ltd., 1897.)

IN these pages the author presents his readers with a popular and general account of the more prominent features of the heavens, and describes how astronomers have been able to gather such information. After a short historical sketch of the founders of astronomy up to the end of the eighteenth century, a series of chapters is devoted to the various constellations, showing how each particular one may be recognised, and at what time of year it is best visible: the diagrams accompanying these will be found very distinct, and undoubtedly useful. The author then devotes a chapter to the character of the astronomer, acting on the idea that the personality of the observer is a powerful factor in his scientific utterances. The illustrations accompanying this chapter are restricted to American astronomers, and will be of special interest to those who know the works, but have not made the acquaintance, of celestial investigators, across the Atlantic. Reference is next made to the astronomer's implements and observatories: in this the great refractors of America, and a description of the preparation of the lenses, are dealt with, followed by a very sparse account of spectrum analysis. A few pages are devoted to the measurement of time, and the general features of the solar surface are next generally described. Some excellent lunar reproductions are inserted in the text relating to the moon and eclipses, and the planets come in for a good share of description, reference being made to most of the recent work done in this branch of observational astronomy. The progress made in celestial photography is well illustrated in those sections dealing with comets, nebulæ and stars; but the information is at times somewhat scanty—as, for instance, the dismissal of stellar spectra in about one hundred lines. As a whole, the book is well worth perusal, and its value is considerably enhanced by the wealth of excellent illustrations throughout. The general reader, as well as the student, will find in it much that is interesting.

The Clue to the Ages. Part I. *Creation by Principle.* By Ernest Judson Page. Pp. xii + 282. (London: Baptist Tract and Book Society.)

THERE are species, varieties, and sub-varieties of human societies and human character, just as there are of structural organisms. Says the author: "The recorded histories of the centuries are as geological strata in which are imbedded the records of the origin of species of character, by which to test, and, if necessary, correct Darwin's theory. Regarding differing ecclesiastical and national types as true species and varieties of character, the question arises—Does the Evolutionary Hypothesis sufficiently account for the Origin of Species? My answer is most emphatically that species of human character have not arisen, and do not arise, according to Darwin's theory." Having proved to his satisfaction that evolution is insufficient to explain social development, the author propounds an alternative theory which he submits to the kind consideration of an indulgent public.

Who's Who, 1897. Edited by Mr. Douglas Sladen. Pp. viii + 823. (London: Black, 1897.)

THIS is certainly a most useful book to have on a library table; for it is a hand-book of not only those who inherit distinction, but also of those who are officially prominent, and others whose ability has brought them before the public. Information may also be obtained regarding the Royal Family, Army, Navy, the Government, Universities, Church, &c.—in fact, all societies and institutions with which we are brought into daily contact. There is also a complete list of the Fellows of the Royal Society, and a useful table of pseudonyms. We notice that the short biographies, which form the greater part of the book, include a large number of scientific men. The book is very neatly got up, is bound in a good flexible cover, and is excellently printed.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* NATURE. *No notice is taken of anonymous communications.*]

The Caucasus.

I AM very reluctant again to trespass on your columns, but "J. W. G.'s" note, in NATURE of April 8, leaves me no alternative. It contains, at least, one assertion which ought not to pass uncorrected in any scientific journal. I refer to the following sentence:—

"The fact that the Caucasian place-names are derived from different languages had not been overlooked; but the rules laid down by the R.G.S. Committee, to which Mr. Freshfield refers, admit the principle in such cases of accepting the spelling of a standard national gazetteer or of official survey maps."

In reply to this statement, I have to point out that the rules adopted and promulgated by the Royal Geographical Society in 1891, and confirmed in 1894, say exactly the contrary. I quote the two rules applicable in the case of the Caucasus, which are those on which I have endeavoured to act.

"The true sound of the word, as locally pronounced, will be taken as the basis of the spelling."

"In the case of native names in countries under the dominion of other European Powers in whose maps, charts, &c., the spelling is given according to the system adopted by that Power, such orthography should, as a rule, be disregarded, and the names spelt according to the British system, in order that the

proper pronunciation may be approximately known. Exceptions should be in cases where the spelling has become by custom fixed, and occasionally it may be desirable to give both forms."

We write of Caucasus and Georgia, not Kavkaz and Grusia. But other legitimate exceptions in the Caucasian Provinces it might be hard to find. The fact that in the case of India the Society, for reasons of convenience, accepted the system, closely kindred to its own, already adopted and embodied in Hunter's Official Gazetteer, can be in no way to the point in the case of the dominions of another Power. I can discover no reasonable ground whatever for the confusion of mind into which my critic has fallen. Douglas W. Freshfield.

Alpine Club, April 9.

"A Gigantic Geological Fault."

In the very interesting description, by Captain A. H. McMahon, of the features of the country on the southern borderlands of Afghanistan, which appears in the *Geographical Journal* for this month (April 1897, p. 393), he gives an account of a remarkable trench, or depression, running in a nearly N.N.E. and S.S.W. direction along the borders of Registan, which he was able to trace for 120 miles, but which may extend for a much greater distance through that wild region, and he clearly identifies it as the line of a large fault dividing a district composed of sedimentary rocks on the east, from one formed of igneous rocks on the west. On reading this account, the resemblance of this line of fracture to that of the Jordan-Arabah Valley at once suggested itself to my mind. The resemblance is nearly complete as regards the latter, from the head of the Gulf of Akabah as far as the northern end of the Dead Sea, at least; except in this respect, that in the case of the Jordan-Arabah fault the sedimentary rocks occur on the west side, and the igneous rocks on the east. But the author has surely been misinformed as regards the statement, that "the length of this fault (which he traced) exceeds that of any fault-line as yet discovered on this earth" (p. 403). As far as actual observation goes, that of the Jordan-Arabah Valley is much longer; for, measured only from the head of the Gulf of Akabah to the base of Hermon, it has a length of 270 miles or more; while there can be little doubt that it ranges still further north into the valley of Cœle-Syria. In the opposite direction, it may well be supposed that it follows the Gulf of Akabah for an unknown distance. It will thus be seen that the fault-line of the Jordan-Arabah Valley is very much longer than that of the border of Registan, described by Captain McMahon, as far as actual observation is concerned. But I am very far from asserting that either the one, or the other, exceeds in length that of any fault-line yet discovered. Edward Hull.

Effects of Electrical Discharge on Photographic Plates.

In your issue of January 21, you published a note of mine on certain effects produced by charged conductors on sensitive plates. In the case of the radiograph of wire skeletons, I find that this is not an electrical effect, but is, in accordance with my alternative suggestion, undoubtedly due to the unequal loading of the film with silver particles, which set themselves in the pattern shown in the illustration when the gelatine is raised to a temperature near its melting point.

The images of coins have been referred to by Mr. Brown and Mr. Sanford in their interesting letters, published January 28 and March 25 respectively (pp. 294, 485).

I am also indebted to Prof. Smith, of Oxford, for a description and specimen of his beautiful "Inductoscript," in which very perfect images of coins and other objects are obtained by charging them inductively.

In cases of brush discharge, such as that of the coins figured in illustration of my note, much of the effect is undoubtedly due to the luminous and ultra-violet radiation; but this seems hardly to cover the whole ground. Both Prof. Smith and Mr. Sanford have got results which seem to point to some more direct electrical action, the latter having secured images of coins imbedded in gutta-percha and other insulators. To test this, I have placed a sensitive plate between two sheets of ebonite about $\frac{1}{16}$ of an inch thick, which were placed upon a brass face-plate, and a coin laid upon the upper ebonite plate. The positive pole of the coil was connected with the brass plate, and the negative with the coin, and current passed for about two minutes. On development, an image of the coin came out, showing the design and a radiating halo, but out of focus and somewhat blurred, as might have been expected, as the coin was separated from the plate by the thickness of the ebonite sheet. This seems to point to some action other than that of the luminous discharge, which was plainly visible on the upper surface of the ebonite round the coin.

It would be interesting to know the arrangement of condenser used by Mr. Sanford. James P'Anson.

Fairfield House, Darlington, April 13.

Curved Knives.

It may interest your correspondent, Dr. Otis T. Mason, to know that the curved "drawing-knife" described by him has representatives in Western (British) India. The Kolis (fishing races) of the Bombay coast wore lately, and some still wear, knives made by local blacksmiths, of which the blade, 2 to 3 inches long, was shaped and edged like that of an English gardener's knife. There was no hilt, but a tang curved reversely to the blade, ending in a little curl. The whole figure was that of a manuscript capital S, with the lower curve heavily drawn and a fine finish at the top. Through the curl was passed a soft lanyard, and the whole worn round the neck, the knife hanging like a locket a little below the collar-bone. The way in which a man, holding the thin tang between the thumb and forefinger, or between two finger-knuckles, would cut anything, from a cable to a fish's head, was the more wonderful, as he would often prefer bringing his breast near the object to unsling his knife. These knives are now passing out of use, displaced by old English and German clasp-knife blades, still without the hilts. The form must be very ancient, as bronze knives or razors of much the same shape are figured in most books about the European Bronze Age, and in Du Chaillu's "Viking Age." I am inclined to suspect a flint origin for this form of tool. Flint flakes in Western India, from Sind to the Konkan, often show a curved inner edge with traces of use. And if any one tries to cut wood with a hiltless flake of the sort, he will find the inner edge the most efficient. The Indian farrier's "drawing-knife" is shaped like a sickle, squarely truncated to avoid the chance of injuring the horse's foot (just as the English farrier's knife is turned to one side for the same reason). Its hilt is a mere roll of coarse tape, but the grip of the hand is often that shown in Dr. Otis Mason's illustration.

The various *hafted* knives of India, with interior edges, belong to another class; but the handle shown in this plate seems to be just an improvement on the simple blades mentioned above, and a very creditable one too. W. F. Sinclair.

102 Cheyne Walk, Chelsea, April 9.

Electrical Vibrations of Mercury.

The following observations were made with a globule of mercury, about $1\frac{1}{2}$ cms. in diameter, placed in a photographic developing dish containing some ordinary tap water, the mercury being well covered with water. A 4-volt accumulator of 6 ampère-hours' capacity supplied the current. Two wires from the terminals served as anode and kathode; the kathode had a short piece of fine wire attached, and this was so adjusted that it only just touched the mercury.

(1) When the circuit was completed by dipping the anode into the water, the mercury, after a few seconds, became visibly flattened.

(2) If the circuit was broken, or the mercury became detached from the kathode, it at once regained its original shape.

(3) When the circuit was completed, and the mercury becoming flattened broke away, it was thrown into a regular and continuous vibration.

(4) The frequency and amplitude of the vibrations depended on the distance of the anode from the kathode, the frequency and amplitude increasing as the anode was brought nearer.

(5) If the current was reversed, thus making the kathode an anode, the vibrations were not produced.

(6) The vibrating mercury generally retained its circular shape, but sometimes it became almost square, or took the shape of a cross, which seemed to be produced by a rapid motion alternating at right angles.

(7) The water was thrown into circular waves, which corresponded to the vibrations of the mercury.

(8) If the circuit was broken, and an interval of time was allowed to elapse, and then again completed, a decided lag was observed between the "making" of the circuit and the flattening of the mercury. If no appreciable lapse of time took place between "make" and "break," the response was instantaneous.

42 Henslowe Road, East Dulwich. Ernest Braun.

REFLECTOR AND PORTRAIT LENS IN CELESTIAL PHOTOGRAPHY.

IT has been much discussed recently, whether the reflector is preferable to a portrait lens in celestial photography. It may be known to the readers of NATURE that I am interested in this subject, since I believe I was the first to use the portrait lens for the purpose of seeking for large and wide-spread nebulæ.

No doubt the reflector has many advantages over the portrait lens—advantages which Dr. Roberts has often dwelt upon. In consequence of the small absorption of light, the lack of the different surfaces, and the absolute correction for chemical rays, the focal pictures with the reflector must theoretically be much better than with the doublet. The two last-named points are especially effective: for the star discs are made much smaller and increase much slower than with the portrait lens. I have shown that the lenses themselves are the reason for the increase of star discs in the film (*Photogr. Corresp.*, 1892), therefore I fully understand the advantages of the reflector.

With my 6-inch Voigtländer portrait lens, the discs of the smallest stars in the Milky Way have a diameter of 6 to 8 seconds of arc; I think with a good reflector such discs may have a much smaller diameter.

I do not know the diameter of the smallest star discs on plates taken with Dr. Roberts' 20-inch reflector; we may believe, however, that in his best pictures the sharpness of the image is much greater than with my 6-inch portrait lens.

As to the light-gathering power—regarding the proportion of aperture to focal length the same in the two cases—there are two reasons why it is greater with the reflector than with the portrait lens. Besides the greater absorption of light in the glass of the lens, in the latter the discs of images are larger, and therefore not so intense. But the reflecting power of the mirror is always soon diminished through the influence of oxidation, and therefore the reflector does not surpass the portrait lens practically as much as would be expected.

The advantages which exist for small reflectors over small portrait lenses increase accordingly to the diameters; the absorption in the portrait lens becomes rapidly greater and the sharpness less, and thus the *large* mirror will surpass *encore plus* the *large* doublet.

In spite of this, the portrait lens is much superior to the reflector for the work of seeking and charting feeble and extended nebulosities.

The lens takes a much larger field of the sky than the mirror. This is known to be the reason why the portrait lens should be used exclusively for the photography of minor planets, of comets, for making charts, and especially or general views of the Milky Way. This last point has been taken up (*Monthly Notices*, R.A.S., vol. lvii. No. 1) by Prof. Barnard against Dr. Roberts. Barnard shows that the portrait lens is far better adapted to give the general structure of the Milky Way than the mirror, in which the field is so small.

I was sure of this from the beginning, and afterwards all my plates showed that there is still another reason for preferring the portrait lens to the reflector; a reason which, depending likewise upon the large field, would alone have decided me to use even a big portrait lens instead of a reflector.

When photographing regions of sky covered with feeble and extended nebulosities, only feeble and extended darker parts are obtained upon the plate. These can only be seen if there are besides these parts other

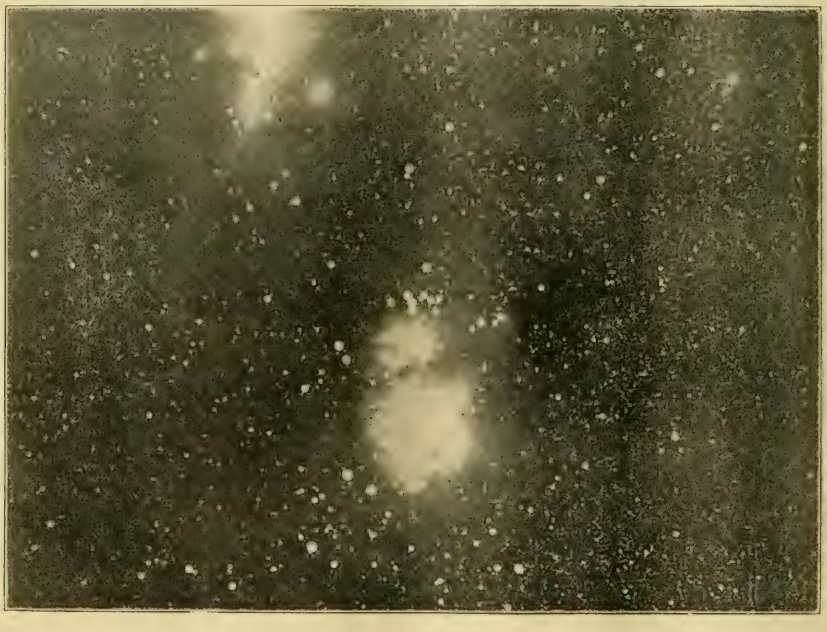

FIG. 1.—The nebulæ of Orion.

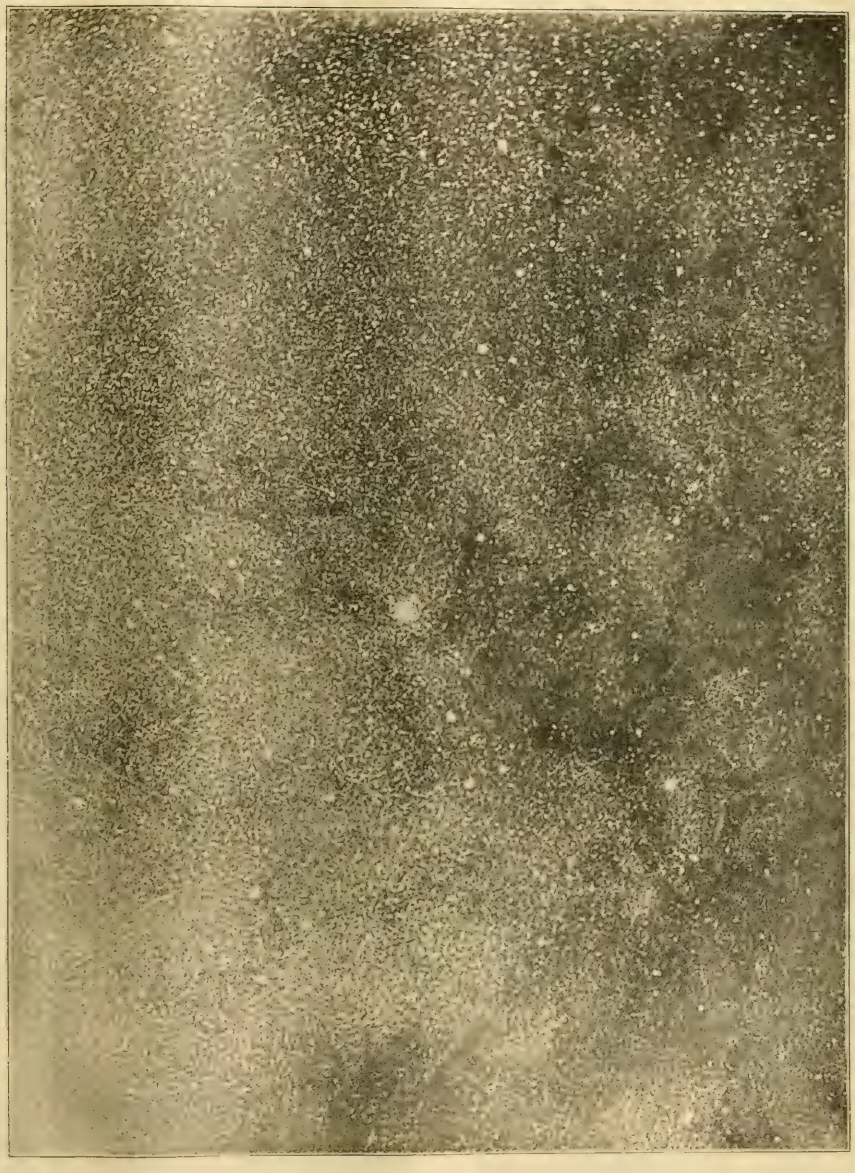

parts on the plate free from nebulous matter, and therefore appearing lighter.

The nebulosities only are clearly visible, if the borders between nebula and dark sky are followed across a large surface. It follows that this can be done only with large fields, and will never be possible with the reflector; therefore, in this case, the portrait lens is preferable to the reflector.

With a mirror I should not have found the large nebulæ in Cygnus, the large nebulosities of Taurus, of Cassiopeia, of Aquila, of Orion, and of many other regions. I only could find them on the ample field of the portrait lens.

The very small doublets—for instance the small lantern lenses, which have been used by myself, and afterwards by Prof. Barnard—are in certain cases inferior to larger lenses. The smaller lenses crowd the nebulous masses, hide the rifts, and consequently make the trains of nebulosity less clear than a slightly larger portrait lens would do.

If the plates are not exposed long enough, various devices have to be employed to discover the faint nebulosities on the plate. One simple way of doing this, is to press the plate in a printing-frame upon smooth white paper, and to examine it in the sunlight. In this way I found the nebulosities in Taurus, and the America nebula for the first time, on plates which were exposed for only a very short time. A second way is to use a monochromatic light to examine the plates; then slight differences in brightness can be easily seen.

Orion was a good subject for the finding of such diffused nebulæ. Besides the well-known nebulæ around ζ and θ Orionis, and besides the many small nebulæ, there are feeble and widespread nebulosities, some of which have been discovered by Profs. W. Pickering, Barnard, and the writer, with the aid of portrait lenses. These would still be unknown but for the portrait lens, because a plate taken with a reflector would cover only a minute part of the nebulosities, and there would be no parts free from nebulosity in this small field, to be compared with the nebulous parts.

FIG. 1.—Nebula of Andromeda.

I may here remark that I discovered easily the interesting connection between the nebulæ of θ Orion and ζ Orion (Fig. 1). This seems a most important example of the connection of two large and far distant nebulæ; and because the connection is effected over a wide field, it promises to bring new light on the knowledge of the situation of the nebulæ in the universe. Fig. 1 is a slightly enlarged print of a plate of this part of the sky, taken with a 6-inch Voigtländer lens of 30-inch focus.

The broad long-spread train of nebulosity, which appears in this marvellous bay running from ζ Orionis nearly in a straight line against S.S.E., becomes broader and broader growing southwards, and at the same time fainter and fainter. It makes a wide curve, and runs much more south than the brighter parts of the θ Orion nebula. Now, in every direction we see streams of nebulosity running from north, east, and south from the ζ nebula to the θ nebula. Especially from the north come down many lacerated and finely-drawn ribbons of nebulosity connecting the ζ Orion nebula with the θ nebula. The most marvellous connection is by the above-named broad stream, which runs much more south than the θ nebula, and passes over to it from south-east in a large arch.

Besides these nebulæ lie very extended relatively bright nebulosities to the west of the θ Orion nebula, connected with it by many streams; and also mighty nebulosities are situated to the east of the circular train, which comes down from ζ Orion nebula. These are likewise connected together at almost every possible place.

The picture is a beautiful and marvellous one, yet we see only the roughest connections and streams.

It needs long-sustained efforts and much work before we shall be able to know this region, so that we can

reproduce the pictures of the portrait lens as a chart of it.

This is an example of what portrait lenses have given us in quite a new direction. If we find out, as in this case, that two such nebulæ are connected in spite of their being far distant on the sky, this gives us the impulse for quite a new comprehension of the universe; and all the theories of this kind have to be given up in favour of a new one.

I gave other examples of such large nebulæ several years ago in *Knowledge*, and perhaps they are still in the memory of some of the readers.

An example of the connection of a cluster with the Milky Way, and the general structure of a part of the same, is given in Fig. 2. The cluster is Messier 11, in Scutum, exposure 3½ hours, enlarged part of the original plate. It will be seen at first sight, that those mighty masses of faint stars and star dust show the most interesting stratifications and connections. The cluster looks like the centre of a moved system. We see here at a glance, that it would have been impossible to get such views of star streams with the small field of a reflector.

I use this opportunity to state that I made last year several improvements in finding and reproducing nebulous masses, using a method of strengthening the image by reprinting it. It is possible—by printing the original plate successively on other plates—to reinforce the feeble contrasts between the nebulosities and the background of sky, so that one can see at a glance such nebulæ on the reproduction, of which the traces are only to be suspected on the original plate. It looks very curious to see side by side the original and the reproduced negative. My friend Prof. Naegamvala, to whom I communicated the method last year, has published something about this matter in the *Journal* of the British Astronomical Association (vol. vii. No. 3). He and Mr. Lunt had great success with the nebula M.8, using this method. The reprinting ought to be done upon slow plates in over-exposing, and, in developing, very slow developers should be used.

I give here (Fig. 3) the twice reprinted reproduction of a plate of the Andromeda nebula, as an example of the results obtained. The original (of four hours' exposure with a 5-inch aplanatic lens, made in 1891) was very faint, so that it would have been impossible to make a good print of it. It is not possible to go further on in this way, because the grain becomes troublesome. But using transferrotype-collodion-paper or dry-collodion-plates, the process can be repeated several times. The process used for reproduction is unable to make a satisfactory comparison between the first and second reproduction of the nebula, so only one illustration is given.

For another example I give the outer-nebulæ of the great Orion nebula (θ), which are reproduced here the first time (Fig. 4). We see many interesting streams of nebulosity all around, which never thus can be given at once by a reflector. The print is from an enlargement of a negative of 4½ hours' exposure, with a 6-inch portrait lens.

Fig. 4.—The surrounding nebulæ of the Great Orion nebula.

In spite of using this small 6-inch lens, nearly all detail visible in brighter parts photographed on Dr. Roberts' photographs is quite well visible here. It must be possible to get, within a certain limit, detailed pictures of nebulæ by portrait lenses. No doubt, a good and large reflector will give much more detail; but the difference between reflector and portrait lens is not so great as is often supposed. The sharpness of the image of the portrait

lens is better than is assumed by various astronomers; I found it about ten times greater than it is given, for instance, by Prof. Wilsing in his recently-published paper in *Astr. Nachr.*, No. 3400.

The weak point in photographing stars and nebulæ is not in the instrument; it is in the plate. We know that the Pleiades are surrounded by wide-spread nebulosities, shown by Prof. Barnard and myself. Now for four years I have been working at a chart of this nebulous region, but it has been impossible to get to an end till now. In this case the plates did not allow it; either they were not sensitive enough, so that I got nothing, or if they were, they had streams or spots looking exactly like nebulæ. I made several dozens of exposures of the Pleiades, some of twelve hours' exposure, containing beautiful nebulosities, but no plate has been sufficient. All of them show, besides the true nebulosities, more or less artificial nebulæ, making it impossible to find out exactly the structure of the true nebulosities. Thus we need often a large number of plates to get the true nebulosities ready for charting. This is now the chief question for celestial photography.

Photographs of small nebulæ taken with portrait lenses often show much detail; for instance, the nebulæ near γ Cassiopeiæ, called by Barnard the "fan-shaped" nebulæ. These nebulæ were photographed the first time

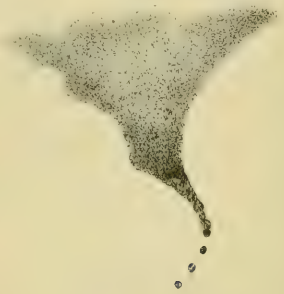

FIG. 5.—Fan-shaped nebula in Cassiopeia.

by myself, December 30, 1893, and described in the *Astr. Nachr.*, No. 3214. Prof. Barnard obtained them several weeks later, and he showed that these nebulæ represent a good example for the advantages of portrait lenses over reflectors in discovering nebulæ, because Dr. Roberts did not find them on his plates. Now these nebulæ seem to me of the greatest importance for the comprehension of the genesis of stars; and especially for the theories of Mr. Lockyer, these will be found very interesting objects. Several years ago I gave in *Astr. Nachr.*, No. 3217, an illustration of one of those nebulæ [$0^h\ 52^m + 60^\circ\ 5'$ (1860)], and the sketch is reprinted here (Fig. 5). I have shown that the nebula looks like a tornado, in the concentrated part of which the stars are formed, and that thus the chain formed by the stars may be understood.

There we have the point where our small portrait lenses fail, and where the reflector finds its place. The lens has found the nebula, and given the first idea of its constitution; but the large mirror will bring out here the details necessary for our knowledge. It is the same as with the small spiral nebulæ, of which Dr. Roberts' plates have shown us the true form.

To me it is quite incomprehensible how it was possible to begin a dispute about the use of the portrait lens in celestial photography. The portrait lens has given us so much, that it is now too late to discuss its efficiency.

The doublet finds the nebulæ—I will not speak of comets, planets, &c.—and throws light upon the ways in which the large nebulous streams spread over enormous parts of the sky. The charting and following of these streams forms now one of the most important problems of astronomy. Therefore this instrument is absolutely necessary for us. It brings us also to a certain high degree of knowledge of the finer detail, though not nearly so high as the mirror. But with portrait lenses not too large we can expose very long, and over several nights, so that we can get traces of nebulæ and stars, which we can never find with the large reflector, because such very long exposures are not quite possible with a reflector, for technical reasons.

For these points the reflector has to recede. It is true the portrait lens will often photograph certain objects as nebulous, which will be found later formed by smallest stars. But the pictures of the reflector show, likewise, at many places nebulosities which, I am sure, are composed of relatively bright stars. An example of this effect has been given by Prof. Barnard, for the case of Dr. Roberts' plates (*Monthly Notices*, lvii. No. 1). The difference between the two instruments in this direction is not a very great one, and because the portrait lens is absolutely necessary to us in so many problems shown here, we have to use it as often as we can for these purposes, and to leave the reflector to work out the finest details of special points.

MAX WOLF.

Heidelberg, Astrophys. Observatory, March 1897.

THE TWENTY-FIFTH ANNIVERSARY OF THE FOUNDATION OF THE NAPLES ZOOLOGICAL STATION.

ON April 14 was celebrated, with great ceremony and *éclat*, the twenty-fifth anniversary of the foundation of the Zoological Station at Naples by Dr. Anton Dohrn. To the general outside public, the eventful day itself was heralded by the appearance in the Bay, just opposite the Zoological Station, of the entire fleet of the Station, drawn up in line, and gaily decked with bunting. This consisted of the two steamers, the *Johannes Müller* and the *Frank Balfour*, and five small fishing-boats. In addition, the Italian Government sent a guard of honour in the shape of a second-class cruiser, the *Fieramosca*, which remained in attendance all day.

In the Station itself all was excitement and expectancy. In the morning, a deputation consisting of one German one Italian, and one Englishman, who were supposed to represent the naturalists of each nationality at present working at the Station, waited on Dr. Dohrn, and offered appropriate congratulations, each speaking in the language of his nation. Dr. Dohrn, on replying, successfully evaded linguistic difficulties by beginning his speech in German, continuing it in Italian, and finishing it in English. The same deputation also waited upon and congratulated Dr. Hugo Eisig, Dr. Dohrn's senior assistant, who has been associated with him since the foundation of the Station.

The grand ceremony itself began at two o'clock. The visitors, on arrival, first assembled in the library, and then passed on to the meeting-room, which was situated on the ground floor of the smaller building. This was the largest room available, and it held about one hundred and twenty people. Needless to say, every available seat was occupied. At one end of the room was a small platform and desk, from which the various speakers in turn delivered their discourses. Just above the desk was hung a specially-painted picture, representing the Bay of Naples, and in the foreground a symbolical figure resting against a block of stone, on which was inscribed, "Al Prof. Dohrn ed ai suoi cooperatori," and the fact of the twenty-fifth anniversary. On a shelf running round the end of the room were arranged the various addresses

and telegrams received by Dr. Dohrn. Amongst others, I noticed addresses coming from Munich, Frankfort, St. Petersburg, Moscow, Danzig, Turin, the Société Helvetiques, and the Society of Naturalists in Naples. England was represented by a beautifully-illuminated address from the Royal Society, and also by addresses from the Marine Biological Association, Plymouth, the Cambridge Philosophical Society, and the Board of Biology and Geology at Cambridge.

The speeches themselves, though very interesting, were somewhat lengthy withal. As the audience consisted mostly of Germans and Italians, the speeches were arranged so as to be spoken more or less alternately in either language. The proceedings were opened by Prof. Todaro, of Rome, who referred at some length to Spallanzani, who had engaged in marine biological work on these very shores. He was followed by Prof. His, who gave some account of the history of the Station since its foundation. He also read an address signed by nearly two thousand naturalists, from almost every country in Europe. The next to speak was Prof. Waldeyer, of Berlin, who brought an address from the Berlin Academy, and who mentioned the fact that he was the first student to work at the Station, at a time when the resources and equipment were very different from those of the present day. He also dilated on the manifold uses, in many departments of science, to which a Marine Zoological Station can be put. Next came the Syndic of Naples, who presented Dr. Dohrn with the freedom of the city; and then Admiral Palumbo, the Under-Secretary of State, made a short speech. The Minister of Public Instruction, who followed, presented Dr. Dohrn with an order, the "Grand ufficiale della corona d'Italia," and brought the congratulations of King Humbert.

Thus far the proceedings had been very stiff and formal, and even solemn in their nature, so the German Ambassador from Rome endeavoured to instil a little humour into his speech. In this there was frequent reference to the Kaiser, who sent his best wishes, and mentioned his interest in science. The Ambassador remarked, also, that Italy and Germany, closely connected by political ties, had an additional bond of friendship in the Stazione Zoologica.

Then came the speech of the day, from Dr. Dohrn himself. This was, of course, spoken in German, but copies of it, printed in Italian, were circulated amongst the Italian members of the audience. This admirable and highly-interesting speech was of somewhat more than half-an-hour's duration. Dr. Dohrn said that he had himself intended to make this day merely an occasion for recalling the memories of persons connected with the Station, and also the scope of the Institute; but his friends had desired to celebrate it with more ceremony, and for this he begged them to accept his most profound gratitude. He referred in very feeling terms to his father, but for whose liberality it would have been impossible to bring his enterprise to a successful issue. Biologists, he remarked, continually speak of protoplasm, the basis of all things living, the substratum of all animal and vegetable life. But there is in man, also, a psychical protoplasm. It was this psychical protoplasm in which was originated the first idea of the Stazione Zoologica, and this he owed to his father. Next to his native forests in Pomerania, the strongest passion of his father was for Italy, with its ancient culture, with the splendour of its renaissance, and its ancient music.

Dr. Dohrn then offered his grateful thanks to the people of Naples for allowing him to found his Station there, his especial thanks being due to the late Profs. Paolo Panceri and Salvatore Trinchese, of the Naples University. It was owing to Panceri's influence with the municipal authorities and the Government that a site for the Station was obtained in the *villa nazionale*. His thanks were no less due to the Italian Government for their moral and material assistance. Fortunately, also, the Station was able to rely upon the tower of strength expressed in the words "Kaiser und Reich." Thus the Emperor William I. presented a considerable gift to the Station; whilst in the early days of its foundation, the time of difficulties, not a year passed but that the unfortunate Emperor Frederick wished to be informed as to its progress. Similarly, also, had the Kaiser William II. shown his sympathies. Also, King Victor Emanuel and King Humbert have extended their protection to the station.

Great, also, are the thanks due to the Imperial Government and the German Parliament. In accordance with an ancient custom, which comes from England, the mother of Parliamentary *régime*, proposals regarding demands on the exchequer may be initiated by the Government. On the strength of a petition signed by Helmholtz, Virchow and Dubois-Reymond, the German Parliament granted a large annual subsidy, which they gradually increased to 2000*l.* a year.

No less was his gratitude due to his English friends, for their help in the grave crisis which attended the Station at its origin. It will be to the lasting glory of the Station that it was largely subscribed to by Darwin. How great, also, were his (Dr. Dohrn's) thanks to his father for his liberality, and likewise to his father-in-law, who allowed him to use his wife's *dot*, which had been destined for furnishing their house, to pay debts on the Station. But the Station was always provided with everything necessary for research, and this appealed much more to his wife's heart than the furnishing of her own house.

It was impossible to thank every one to whom thanks were due, but to three corporations—the Academy of Sciences of Berlin, the British Association for the Advancement of Science, and the Smithsonian Institution of Washington—the prosperity of the Station was largely due, for their subsidising "tables" at the Station.

Finally, in the name of the Stazione Zoologica, were especial personal thanks due to his collaborators, particularly to Dr. Hugo Eisig, the first collaborator with him at the Station, and one who threw in his lot with him when the actual foundation of the Station was yet but a chance. And lastly, to all those who by their presence had set a sanction on these festivities, Dr. Dohrn wished to offer his most profound thanks for the great honour they had done him.

This brought the meeting to a close. In the evening the guests and members of the staff of the Zoological Station were entertained by Dr. Dohrn at dinner, at which in all some sixty people sat down. The speeches were again many in number, but were shorter and more humorous in nature. H. M. VERNON.

EDWARD DRINKER COPE.

THE death of Prof. Cope, of Philadelphia, which took place on April 12, has removed the man who, since Louis Agassiz, has been the greatest influence in American biology.

Born in Philadelphia on July 28, 1840, he passed from the University of Pennsylvania to Heidelberg, where he took the degree of Ph.D. in 1864. In that year he was appointed Professor of Natural Science in Haverford College in his native city, but resigned the post three years later, partly by reason of ill-health. During the years 1871 to 1873 he joined many geological exploring expeditions to Kansas, Wyoming and Colorado, and from 1873 to 1878 he was engaged in field-work with the Wheeler Survey of the United States Government. Th Hayden Survey also had his services as vertebrate palæontologist. The results of his work in connection with these Surveys were published by the Government in many fine volumes—*e.g.* "The Vertebrata of the

Cretaceous Formations of the West," 1875; "The Vertebrata of the Tertiary Formations of the West," 1883; and "The Extinct Vertebrata obtained in New Mexico," 1877. It was in recognition of this work that, in 1879, he was awarded the Bigsby Medal of the Geological Society of London. The loss of a portion of his private fortune led Cope, in 1889, to accept the professorship of Geology and Mineralogy at Pennsylvania University. This post he held till 1895, when he was transferred to the professorship of Zoology and Comparative Anatomy. In that year also he was elected President of the American Association for the Advancement of Science. From 1878, with A. S. Packard, and from 1887, with J. S. Kingsley, he was a chief editor of the *American Naturalist*, a journal that has had its periods of financial difficulty and irregular publication, but which, under Cope's direction, has always been interesting, vigorous and independent, playing a much-needed part in a country where so much scientific work is under the control of political placemen.

Cope's zoological work has lain among the Vertebrata, especially their lower Classes. Beginning in 1859, with a paper on "The Primary Divisions of the Salamandridæ," published by the Philadelphia Academy, the stream of contributions poured out by him has reached a total of over four hundred. By his study of recent and fossil forms in conjunction, he has thrown much light on the history of the Reptilia and Amphibia, leading to many profound changes in classification. Two of his most important essays in this direction were those published so long ago as 1865-66: "On the Primary Groups of the Batrachia Anura" and "On the Arciferous Anura." His work on the extinct ancestors of the Amphibia, the direct progenitors also of the Mammalia, was some of the most successful and suggestive that he accomplished. His important paper on "The Systematic Relations of the Fishes" was published by the American Association in 1871; much of the material on which this was based was the famous collection of skeletons made by Prof. Josef Hyrtl, of Vienna, and acquired by Cope for his own museum. Cope was one of the first to deduce the Ungulata from ancestors with quadri-tubercular molars, and with five-toed, plantigrade feet. This was in 1874; and it was he too, who, some ten years later, was the first to maintain that this type of molar in the upper jaw was derived from a tri-tubercular type, while in the lower jaw it was derived from a quinque-tubercular type, or a tri-tubercular type with a heel supporting two additional tubercles. The additions to, and the discussions that have taken place around, this theory are well known. Cope's discovery of Phenacodus, the celebrated fossil ancestor of the Ungulata, proved in his masterly hands "an important event in the history of our knowledge of the evolution of the Mammalia." The sub-order to which it belongs, the Condylarthra of the Lower Eocene, "stands to the placental Mammalia in the same relation as the Theromorphous order does to the Reptilian orders. It generalises the characteristics of them all, and is apparently the parent stock of all excepting, perhaps, the Cetacea."

It was not, however, Cope's technical zoological work in the domain of Vertebrata, excellent though it was, that made him such an influence in American biology; it was his constant application of his results to wider philosophical problems, especially of evolution, both physical and metaphysical. He, more than any one (though the name of Alpheus Hyatt should not be passed by), has been the founder of that peculiarly American school of thought which has no doubt met with much opposition on both sides of the Atlantic, but which nevertheless has promoted discussion and investigation along many lines. Cope's main contributions to the philosophy of biology were first brought together in that volume of suggestive essays entitled "The Origin of the Fittest" (Macmillan: London and New York, 1887), while his conclusions were summarised, and his present position stated in the "Primary Factors of Organic Evolution" (Open Court Co., Chicago, 1896). That position, as was abundantly evident from Dr. Russel Wallace's review of the last-named book in NATURE (vol. liii. p. 553), did not win the approval of our English ultra-Darwinians, nor, indeed, were the views of the American school easily approved by Darwin himself. But abuse and ridicule cannot hinder the admission that the conclusions (or speculations, if you will) of Cope and others did lead to the discovery and scientific coordination of many undoubted facts, having much bearing on questions of descent. Moreover, many of Cope's audacious hypotheses are now the commonplaces of evolutionists. It is nearly thirty years since his establishment of the doctrine that the development of new characters has been accomplished by an acceleration or retardation in the growth of the parts changed; an idea expressed independently by later workers as the earlier or later inheritance of acquired characters (Cænogenesis, Haeckel). Thus, the adult of an ancestral individual is the exact parallel of a younger stage in its descendant—a limitation of, and yet an advance on, Von Baer's statement of inexact parallelism. Cope, too, was the first to point out that genera—as genera then were understood—were "homologous groups" descended from other "homologous groups"; as we now say, genera are polyphyletic. Retaining the old boundaries of a genus, he regarded it as a grade of evolution. Nowadays there are some who maintain such orders, families and genera, though fully appreciating their polyphyletic origin; while others believe that a group of organisms once proved polyphyletic can no longer be regarded as a unit of classification. These latter workers seek to classify organisms according to their true lines of descent, and they therefore elevate as diagnostic other characters than those so regarded by their predecessors, characters as a rule less obtrusive and of less physiological importance. Whether the older view of Cope, powerfully expressed by Huxley in our own country, or this newer view ultimately prevail, the credit of first putting the problem is due to Cope.

More Lamarckian than Lamarck, Cope rendered the "besoin" of the French philosopher by "effort," regarding animals as in some sort working out their own salvation. The definiteness of variation, in which he believed, and the definiteness of evolution, which all accept, he imagined to be due to the action of a "growth-force" ("bathmism"), thus approaching the views of Naegeli. This force acts, according to Cope, through a kind of unconscious memory, with which faculty the reproductive cells are endued. Thus, as the result of his apparently mechanical conception of the details of evolution, he came at length, along a road that was all his own, to the conclusion of many a philosopher: "that consciousness as well as life preceded organism, and has been the *primum mobile* in the creation of organic structure . . . that the true definition of life is, *energy directed by sensibility, or by a mechanism which has originated under the direction of sensibility.*"

F. A. B.

NOTES

IT has been felt by many entomologists, for some time past, that several of our more interesting and local British insects are in danger of extermination from over-collecting. Accordingly, the Council of the Entomological Society of London appointed a representative Committee to consider the matter. The Committee found themselves unable to recommend any means of affording protection by enactment, as has been done for birds, or even by approaching landowners to induce them to check collecting on property where such species occur. In many cases such insects are found on poor and uncultivated lands belonging to small proprietors, to whom the presence of an army of collectors is a source of profit. It was suggested, however,

that the opinion of entomologists might be stimulated, and an impulse given to their endeavours, by the formation of an association for the protection of such insects. Accordingly, such an association has been formed under the auspices of the Entomological Society, and the following memorandum has been numerously signed. "We the undersigned, being desirous of protecting from extermination those rare and local species of insects which are not injurious to agriculture nor to manufactures, do hereby agree, by our own example and by the exercise of our influence over others, to discourage the excessive collection and destruction of those species of insects which, from their peculiar habits, are in danger of extermination in the United Kingdom. We further agree to accept for the purposes of this Association such list of species in need of protection as shall be drawn up, and, if necessary, from time to time amended by the Committee of the Entomological Society of London appointed to that end." The Association is open to any one interested in the preservation of our indigenous insect-fauna. The Hon. Secretary is Mr. C. G. Barrett, 39 Linden Grove, Nunhead.

MISS CATHERINE WOLFE BRUCE, of New York City, to whom astronomy all over the world is indebted for liberal and intelligent benefactions, proposes to found a gold medal, to be awarded not oftener than once a year by the Astronomical Society of the Pacific, for distinguished services to astronomy. The medal is to be international in character, and may be given to citizens of any country, and to persons of either sex. The design for the obverse of the medal is the seal of the Astronomical Society of the Pacific. The medal is to be 60 mm. in diameter. The reverse is to bear the inscription: "This medal, founded A.D. MDCCCXCVII, by Catherine Wolfe Bruce, is presented to —— (name) for distinguished services to Astronomy —— (date)." The Astronomical Society regularly awards a bronze medal, also, founded in 1890 by the late Joseph A. Donohoe, for the discovery of each unexpected comet.

THE fourth annual exhibition of the New York Academy of Sciences was held in the Museum of Natural History, on April 5 and 6. Exhibits were made in fourteen departments; but as the catalogue fills 54 pages, limits of space forbid us giving even an enumeration of the more important. The astronomical exhibit included reproduction of plates of clusters and nebulæ, taken at Arequipa, Peru, with the Bruce photographic telescope; prints from photographs of stars, at the Yerkes Observatory of the University of Chicago; and copies of photographs of the moon, at the Lick Observatory, the latter including negatives from enlarged photographs used in making the Lick Atlas of the Moon, which is to contain a map 36 × 38 inches in diameter when completed. Conspicuous in the chemistry exhibit was an array of electric furnaces, including the one used by Moissan in his address before the Academy last October. In the electrical exhibit were included some fine pieces of apparatus, notably Pupin's circuit-breaker and induction-coil, which gives a 30-inch spark. It would require a separate article to do justice to the section of physics, owing to the many new and valuable forms of apparatus shown. One of the exhibits consisted of a row of seven Bunsen burners, with aluminium tubes, to show (*a*) the seven spectrum colours with the evaporated salts; (*b*) to produce monochromatic light in considerable quantities; (*c*) to produce a pure Bunsen flame of great intensity as a light for photography, and illustrating its high actinic intensity; (*d*) to heat long tubes, as a substitute for a combustion furnace. Among the exhibits in the zoological section were a map and a relief model of the Zoological Park of New York City, which has finally been definitely located in Broux Park, in the trans-Harlem portion of the city, a locality well adapted for the purpose. A salient feature of the exhibit in this section was the large and diversified collection from the Pacific Coast, made by the Columbia University Expedition of 1896.

WE regret to see the announcements of the deaths of Dr. Eduard Freiherr v. Haerdtl, professor of theoretical astronomy in the University of Innsbruck; Dr. J. Breitenlohner, professor of meteorology and climatology in the Agricultural High School, Vienna; Dr. A. A. van Bemmelin, director of the Zoological Garden at Rotterdam; and Dr. J. F. James, known for his writings in palæontology, botany, and geology.

NOTWITHSTANDING rather boisterous weather, the usual Easter expeditions of the Liverpool Marine Biology Committee have been carried on with success, and the Port Erin Biological Station has never been so full of workers as it has been, and will be, during the whole of the present month. During the actual Easter vacation, the rather limited accommodation has been more than fully occupied. The Lancashire Sea-Fisheries steamer, *John Fell*, has been at Port Erin, and several dredging excursions have been made in it. Spawning fish were procured to the west of the Isle of Man, and the tanks in the Biological Station now contain developing lemon soles and witches, and a cross between the megrim and the cod.

THE success which has attended in Germany the introduction of the system of "pot experiments," as a means of elucidating problems of agricultural science, has at various times engaged the attention of the Chemical Committee of the Royal Agricultural Society. More especially has this been the case, since the bequest made to the Society by the late Mr. E. H. Hills—"for the investigation of the value and uses of the rarer forms of ash in the cultivation of crops for the use of stock and for human food"—called for the setting on foot of a definite plan of experimental inquiry. With a view of seeing how this inquiry could be best carried out, Dr. Voelcker visited the Agricultural Experimental Stations in Germany, and, acting upon his advice, the Chemical Committee have recommended that the inquiries directed under the Hills Bequest be carried out by the system of "pot experiments," in conjunction with "field experiments," as already conducted by the Society at the Woburn Farm. The sum of 1035*l.* required to establish the pot-culture station has been voted by the Society, and it has also been decided to make an annual grant of 200*l.* to the Chemical Committee to supplement the annual income of 200*l.* from the Hills Bequest, and so enable researches other than those covered by the bequest to be carried on at the same time. The report of the Chemical Committee will be found in the current number of the *Journal* of the Royal Agricultural Society.

AT the last meeting (April 14) of the Russian Geographical Society, Baron Osten Sacken read a telegram which he had received from Sven Hedin, the well-known Swedish traveller in Central Asia, announcing that he had crossed Tibet (Northern Tibet) by following a route which lies somewhat to the south of General Pyerstoff's route; during that journey he discovered 23 new salt lakes, four of which are of considerable size. Notwithstanding the great difficulties of the journey, and the loss of 44 beasts of burden out of 50, all collections are safe. From Tibet, Sven Hedin went through Mongolia to Pekin, and towards the end of May he expected to be in St. Petersburg.

THE month of March is proverbially stormy, and this year it was exceptionally so, as not less than seventeen distinct depressions, or areas of atmospheric disturbance, were experienced over these islands, and in some cases the storms were of exceptional violence. The Pilot Chart of the North Atlantic Ocean, published by the Hydographic Office of Washington, states that the month was marked by some exceptionally severe weather over the North Atlantic, especially in the higher latitudes, where the gales followed each other so rapidly that the bad weather

was almost continuous, while on some days a full hurricane was recorded. A few of the captains of vessels reported that they had never before encountered such a long period of unusually severe weather. A glance at the chart shows that at least three of the storms crossed from the American to the British coasts. It is interesting to note that the barometric pressure in the vicinity of the Azores, from February 18 to March 14, was constantly above the normal, varying from 30·3 to 30·7 inches; consequently the weather during the same period for that region, and to the southward, was generally fine, the cyclones, or low-pressure areas, following the usual course of passing to the northward of the Atlantic anti-cyclone or area of high barometric pressure.

PROF. H. C. BUMPUS has critically examined more than 1700 eggs of European and American sparrows, in order to determine the differences between them. The results of his observations were recently communicated to the American Morphological Society. It was found that the American eggs presented a much greater amplitude of variation, both in shape and colour, than the European, that they were smaller, and were also of a strikingly different shape. The large proportion of extreme colour variation found to exist in the case of American eggs is not only interesting in itself, but when the figures are compared with those representing extreme variation in *shape*, the significance of both results is enhanced. Not only is the preponderance of variation among American eggs very obvious, but in both cases, in shape and in colour, it is almost precisely the same. Prof. Bumpus concluded that the data, whether gathered from comparisons of length, ratio of breadth to length, shape or colour, all point in the direction of a general structural modification. The observations have thus an important bearing upon the current theories of degeneration, panmixia, &c.

IN connection with the paragraph referring to injurious effects apparently produced by X-rays (p. 541), Mr. J. Lynn Thomas, assistant surgeon to the Cardiff Infirmary, calls our attention to a note he contributed on the subject to the *British Medical Journal* (March 27). He is of the opinion that these affections are the result of the strong currents in the vicinity of the tubes, and not due directly to the X-rays. Mr. Thomas also says he has noticed that different regions of the glass of a Röntgen lamp in action are under varying electrostatic stresses; the dark half of the lamp, as a rule, attracts light bodies, such as pith-balls, more strongly than the half through which the X-rays emanate. Sometimes the pith-balls are attracted and repelled at a great speed from the glass on the dark side, whilst they are attracted only upon the apple-green side.

THE bacteriological diagnosis of typhoid fever, as such, has long been a matter of difficulty; but since the introduction of Widal's ingenious application of Pfeiffer's sero-diagnosis of cholera, there seems to be a hope of obtaining some definite clue to the bacterial verification of this disease. Widal takes the blood of a patient suspected to be suffering from typhoid fever, and he mixes ten drops with a recent broth-typhoid-culture, and examines a drop of this mixture under the microscope. If the blood is really derived from a typhoid patient, the bacilli, instead of presenting the usual appearance, are seen to be gathering together in innumerable small heaps throughout the microscopic field. This behaviour of typhoid bacilli is claimed by Widal to be specific to the presence of typhoid blood, and is not exhibited in the presence of blood taken in other kinds of disease. The power of typhoid blood to produce this characteristic result on the bacilli is dependent upon the condition of the patient, for as recovery progresses it is not so marked; thus, whereas during the illness the reaction is visible when only one drop of blood is added to sixty or eighty drops of typhoid broth, at a later stage of recovery it will not bear so much dilution, and the proportion varies from one drop of blood to twenty, ten, or even less of broth. Prof. Pfuhl has made many interesting control experiments in typhoid diagnosis by means of Widal's method, and fully confirms his results; he has, moreover, succeeded in still further simplifying the process, and describes his work in a recent number of the *Centralblatt für Bakteriologie*.

THE scientific exploration of lakes has been renewed in Russia by the exploration of Lake Chudskoye, or Peipus, in the lake district of North-west Russia; and Lake Charkhal, which lies in the Kirghiz Steppe, to the south-east of Uralsk, and has thirty-two miles of circumference. The results of both are given, with maps, in the last number of the *Izvestia* of the Russian Geographical Society (xxxii. 4). Lake Chudskoye was studied in detail, as regards the configuration of its bottom, the distribution of temperature in its water, and the chemical constitution of its bottom deposits. As to the exploration of Lake Charkhal, by several members of the Ural Naturalists' Society, it may be taken as a model for similar studies. It was made by several persons at once, and while some of them mapped the lake and the surrounding country, others measured its depths, and others again studied its fauna and flora. The chief point of interest with regard to the fauna is that the herring which was found in the lake was not, as subsequent comparisons proved, the common Caspian herring (*Clupea Caspia*, or *Cl. kessleri*), as might have been expected, but was nearest to the small herring which inhabits the northern tributaries of the Black Sea, and was described by Nordmann, in his *Faune pontique*, as *Clupea cultriventris*. A special variety is consequently established: *Cl. cultriventris*, var. *Tscharchaliensis*. The question now arises, how could it have penetrated into Lake Charkhal? Occasionally the lake is still in communication with the Ural River: so it was in 1887; but the *Cultriventris* herring, which is a brackish-water species, is never met with either in the Caspian Sea or in its tributaries. The most probable hypothesis would thus be that Lake Charkhal is a *Relictensee*, as German geographers say; that is, a remainder from the old Ponto-Caspian Sea. The Charkhal *Leuciscus rutilus*, var. *Heckelii*, is also nearer to the Black Sea variety than to the Caspian variety. Passing by other interesting remarks about the fauna of this lake—its ice formation, the oscillations of its level, and fishing (3000 to 17,000 cwt. every year)—we only remark that its flora is extremely poor; no living algæ could be obtained by dredging, but the bottom of the lake is full of decaying plants, carried thither by the rivers.

THE influence of music upon the respiration, the heart, and the capillary circulation is the subject of a paper, by MM. A. Binet and J. Courtier, in the *Revue Scientifique* (February 27). Experiments were made upon a well-known musical composer, and the investigators endeavoured to determine effects produced by musical sound alone, as distinct from those due to emotions aroused by pieces associated with dramatic incidents or words. Isolated notes, chords in unison, and discords were first tried. Both major chords struck in a lively manner and discords quickened the respiration, the latter more especially. Minor chords tended to retard respiration. When melodies were tried it was found that all, whether grave or gay, produced quickened respiration and increased action of the heart. The lively tunes produced the greatest acceleration. Where the sound was wholly uncomplicated by emotional ideas, as in single notes or chords, the heart's action was accelerated, but not in so marked a degree as when a melody either grave or gay was played. During operatic pieces, or those well known to the subject, the acceleration attained its maximum. The influence of music on the capillary circulation was tested by a plethysmograph attached to the right hand. The capillary tracings showed that a slight

diminution of pulsation was usually produced by musical sounds, the effect being very small when sad melodies were played, but well-marked when lively airs were played.

The popularity of Darwin steadily grows in Russia—the last edition of his chief works, by Madame Popoff, being evidently intended for a very large circulation. It includes, in two octavo volumes, the autobiography, the voyage of the *Beagle*, the origin of species, the descent of man, and the expression of the emotions, translated from the last editions by Profs. Beketoff, Timiryazeff, and A. Kovalevsky, with a portrait of Darwin, and is sold at the very low price of nine shillings (4 roubles 50 copeks) for the two volumes. Another edition of separate works of Darwin is published at the same time by a scientific review (*Nauchnoie Obozreniye*). It is also worthy of note that an abridged translation of Buckle's "History of Civilisation," very well produced in one volume by M. Notovich, and published in a cheap two-shilling edition, went through nine editions, which were rapidly followed by five one-shilling editions.

The evolution of money is a fascinating study, and has been ably dealt with by Prof. Ridgeway in his "Origin of Metallic Currency and Weight Standards." The last contribution to this history is a paper, by Dr. A. Götze, in *Globus* (Band. lxxi. p. 217), in which he shows that some silver bars, excavated by Schliemann from the second lowest layer at Hissarlik, are of the same general form as the flat bronze axe-heads. Their shape precludes their being ornaments, and the material of which they are made prevents their having been used as implements; they were, therefore, probably used as a medium of trade. Numerous bronze axe-heads have been found, along with ring-money, in such a way as to suggest that they were employed as a medium for barter. The conclusion, therefore, is that the actual axe-head formed a popular unit for barter. This was later copied in silver, and even in iron, as Dr. Götze proves, to serve as a regular currency; the final term in the series, as Prof. Ridgeway has pointed out, is the axe-inscribed coinage of Tenedos. Dr. Götze also suggests that the "tongue of gold," looted by the luckless Achan from Jericho (Joshua vii. 21, 24), was a similar golden model of a bronze celt or axe-head.

The Anthropological Reports of the Horn Expedition to Central Australia forms not the least valuable result of that notable expedition. Dr. Stirling undertook the anthropological investigations of the Arunta tribe in the McDonnell Ranges, and he has performed his task in a very satisfactory manner. Careful observations, such as these, of a tribe as yet scarcely influenced by civilisation, cannot fail to be of value, even though the opportunities afforded to the explorers were not as ample as could have been wished. We learn that Prof. Baldwin Spencer has since spent several months with this tribe, and his investigations will doubtless supplement those of the Horn Expedition. Dr. Stirling has wisely incorporated some very valuable ethnographical notes by F. J. Gillen, special magistrate and sub-protector of aborigines. In addition to observations on the social organisation, religion, initiation and other ceremonies, corrobboree, and habits of life, the ornaments, weapons, and implements are carefully described. The gesture language is recorded and illustrated by sketches. Three coloured plates are devoted to representations of rock drawings. One very satisfactory feature of the Report is the prominence given to physiological and medical observations; few travellers have the necessary knowledge of, or interest in such matters. The Report is illustrated with twenty capital plates; many of these are half-tone blocks from photographs by Mr. Gillen. Some of these illustrate various ceremonies, the initiatory rites being the most fully represented. This is just the class of work that is so urgently needed at the present day, and we trust that other wealthy Australians will feel it their duty to fit out anthropological expeditions before it is too late.

The *Annales* of the Central Physical Observatory of St. Petersburg for the year 1895, forming two large quarto volumes, have just been issued. They include an appendix, recommended by the recent Meteorological Conference in Paris, viz. a list of the periodical publications in Russia containing meteorological observations. By direction of the Imperial Academy of Sciences, the explanatory text is now in French, instead of German, and the preface contains a useful note upon the French orthography of Russian geographical names. This will be of much assistance in transliteration and pronunciation. Somewhat similar directions were given in our columns on February 27, 1890; notwithstanding this, we generally find that in English the equivalent for the Russian sound *zh* is rendered by *j* (which would be correct in French), and that *v* is rendered by *w* (which would be correct in German). On July 1 a fire unfortunately occurred in the building for absolute magnetic observations, and most of the instruments were destroyed, but the records were continued in another building with other instruments. The daily weather chart issued by the Central Physical Observatory extends over an immense area, embracing Vardö, in latitude 60° N.; Malta, in the south; the west coast of Ireland, and the limits of Eastern Siberia. Telegraphic reports are received from 186 stations, and weather charts are constructed thrice daily; when necessary, storm warnings are issued to the ports in the Baltic, the Black Sea, and the Sea of Azov. The new Director of the Russian Meteorological Service is General M. Rykatchef, well known as the author of several valuable discussions in maritime meteorology.

One of the most important functions of the Agricultural Experiment Stations in the United States, is to give farmers a better knowledge of the scientific principles underlying their work. To this end two excellent little *Bulletins* (Nos. 139-140) have lately been distributed by the Michigan State Agricultural College Experiment Station. Their subjects are: "Bacteria: what they are, and what they do"; and "Ropiness in Milk"; and the author is Dr. C. E. Marshall. The science of bacteriology has entered into such an intimate relation with the farmer, because of its connection with the dairy, the soil, the diseases of animals and plants, and his surroundings, that some knowledge of it has become indispensable to him, if he wishes to keep up with the times. This knowledge the Michigan Experiment Station proposes to give to the agriculturists of the State by means of short and simply-written bulletins, to be issued from time to time. The first bulletin of the series contains a good general account of bacteria, and the means of studying them. This paves the way for the reports of experiments, such as are contained in the bulletin on ropiness of milk. The Station has, in fact, undertaken to publish, by means of these bulletins, a general survey of bacteriology, with special reference to those phases of the science applicable to agricultural interests. The influence of such bulletins as these, in educating the farmer, cannot be over-estimated. It would be to the advantage of British agriculture if useful and accurate scientific information of the same character could be disseminated by agencies similar to the agricultural experiment station in the United States.

The additions to the Zoological Society's Gardens during the past week include two Grey Ichneumons (*Herpestes griseus*) from Ceylon, presented by Mr. R. J. Davis; a Bauer's Parrakeet (*Platycercus zonarius*) from Australia, presented by Dr. Clement Godson; two Common Cassowaries (*Casuarius galeatus*) from Ceram, deposited; four Shovellers (*Spatula clypeata*), three Common Teal (*Querquedula crecca*), European purchased.

OUR ASTRONOMICAL COLUMN.

REFRACTION AND THE APPARENT DIURNAL MOVEMENTS OF STARS.—The question of the apparent change of positions of stars due to refraction as the hour angle varies, becomes of importance when long intervals of time are taken into account. In photographing the stars, it is generally usual to "stand by" and make all the necessary small adjustments, due to atmospheric refraction, with the hand. A method has, however, been recently suggested and worked out by Dr. A. A. Rambaut, by which the rate of the driving clock may be so adjusted as to take into account these minor discrepancies when a high state of accuracy is desired for stars at large hour angles (*Monthly Notices*, vol. lvii. No. 2). This method does not, of course, take into consideration local or temporary changes in the refraction, but the perfectly regular and systematic change as the star increases or decreases its altitude. For a telescope to follow a star with absolute precision, a clockwork must be constructed which would drive the instrument at an ever-varying rate according to the formula given by Dr. Rambaut. This, however, cannot be practically achieved, and would, further, be unnecessary, as a close approximation is all that is needed in practice. By a system of curves obtained from the above-mentioned formula, and treated graphically, it has been found that a uniform rate, *if suitably chosen*, will not in ten minutes introduce an error amounting to one-twentieth of a second, which is within the limits of the accidental errors of a good equatorial clock. By prolonging the exposure beyond the period for which a uniform rate is admissible, the rate must be altered to one now more suitable. A series of weights, skilfully employed in controlling the action of a pendulum in connection with the driving clock, will allow the different rates to be easily produced. Dr. Rambaut describes a graphical method for obtaining the length of exposure during which a uniform rate may be used. This he finds most convenient in practice for short exposures, and he relates that he can turn his telescope, with the greatest confidence, from a star at its upper culmination, to follow which a star must lose at the rate of from 18 to 100 seconds or more a day, and one at its lower culmination, gaining at the rate of 70 or 80 seconds a day, and he finds "the telescope will follow both with equal accuracy." It may be remarked that this method is practically intended to be utilised when photographs for the detection of stellar parallax are in question, as it is only then that they must be obtained when the stars have a considerable hour angle.

"BULLETIN ASTRONOMIQUE DE FRANCE."—The April number of this monthly contains, among other things, an interesting article, by Camille Flammarion, on the planet Venus, more special attention being paid to the observations which have indicated the presence of an atmosphere. There is also an account of Mr. Percival Lowell's recent observations on the surface markings, and the subsequent determination of the period of rotation, mentioned previously in this column. *A propos* of our note last week, on the question of the adoption of France of Greenwich time, we find that the following resolution was voted by the assembly at the meeting of the French Astronomical Society, on March 3 last, the proceedings of which are here recorded:—"La Société astronomique de France, considérant qu'au Congrès de Washington la proposition du méridien de Behring, qui avait un caractère eminemment géographique, impersonnel et d'ordre universel, n'a pas été adoptée, ne juge pas à propos d'en adopter un autre, qui n'a à aucun degré le caractère auquel la France est toujours restée fidèle dans les réformes dont elle a pris l'initiative." This number of the *Bulletin* contains also several communications relating to the moon, and another beautiful reproduction from one of Loewy and Puiseux's lunar negatives is given, which, for amount of detail and fine contrast, is strikingly beautiful.

PROF. EDUARD HAERDTL.—The Professor of Astronomy at Innsbruck, Prof. Eduard Freiherr von Haerdtl, whose death (*Astr. Nach.*, No. 3416) we regret to record, was born in the year 1861 at Penzing, near Vienna. After finishing his Gymnasium studies in 1880, he selected mathematics and astronomy as his chief pursuits at the Vienna University. He was one of the most apt pupils of Th. von Oppolzer, whose work he vigorously took up, and afterwards so ably continued. In 1892 Haerdtl was promoted to the Professorship of the Innsbruck University. Endowed with a great capacity for carrying out astronomical computations, his dissertation "Beiträge zur Assyrischen Chronologie" was followed by other publications, chief of which was the investigation of the movement of Winnecke's comet. The prize of the Copenhagen Academy of Sciences he won with an interesting essay, entitled "Skizzen zu einem speciellen Fall des Problems der drei Körper," after which he busied himself with the terms of long period in the movement of the moon, and shortly before his death with Winnecke's comet again. Full of such promise, and cut off at the early age of thirty-six, not only has astronomical science lost a man who seemed destined to enrich her with many valuable contributions, but his circle of friends mourn the loss of a kind and true "Kamerad."

ON ELECTRICAL PROPERTIES OF FUMES PROCEEDING FROM FLAMES AND BURNING CHARCOAL.[1]

§ 1. MANY experimenters have investigated the electrical properties of flames and incandescent solids. The methods usually employed have been (1) to examine the electric conductivity of different parts of the flame;[2] (2) to measure the difference of potential between platinum wires in different positions in the same flame;[3] (3) to find the leakage of a charged conductor when placed near, or in view of, a flame or an incandescent solid;[4] (4) to observe the leakage of a conductor, raised to a red or white heat, by an electric current, and electrically charged while it is surrounded by different gases;[5] and (5) to observe the production of electrification or diselectrification by a glowing wire, through which a current is passing, in neighbouring insulated conductors separated from it by different gases.[6]

§ 2. This short communication divides itself into three separate inquiries: (1) to test by one of our electric filters[7] the electric quality of the fumes from different flames and burnings (this method has not, we believe, been tried before); (2) to observe the difference of potential between a copper plate and a zinc plate when the fumes from different flames and burnings at different distances from the plates passed between them and round them; and (3) to observe the leakage between two parallel metal plates with any difference of electric potential when the fumes from flames and burnings were allowed to pass between them.

§ 3. To test the electrification of fumes from different flames and burnings, the arrangement shown diagrammatically in Fig. 1 was used. The flame is kept burning at the mouth of a large vertical iron funnel A, closed at its upper end; and the heated air, along with the products of combustion, is drawn off by an air-pump through a small aperture, B, near the upper end. Before reaching the pump the air has to pass through three circular pieces of brass wire gauze, D, one centimetre apart, which are fixed across the funnel about 5 centimetres below the exit tube B; and through a worm of block-tin pipe, 90 centimetres long, which is kept surrounded by cold water in a vessel C. The electrification was tested by a quadrant electrometer (sensitiveness of the electrometer III scale divisions per volt), and an electric filter F. The filter F was of block-tin tube, 5 centimetres long and 1 centimetre bore, and full of fine brass filings kept in position by a plug of cotton-wool and a piece of brass wire gauze at each end. Between the filter and the air-pump is a T-shaped piece of glass tubing with lower end of the vertical tube dipping into a basin of mercury. This served as a pressure gauge to indicate the difference of air pressures on the two sides of the filter when the air-pump was worked. The flame, the iron funnel, the worm, and the case of the electrometer are all metallically connected.

§ 4. The following flames and burnings were tried :—

(1) Candle.
(2) Paraffin lamp.
(3) Spirit flame.
(4) Portable electrometer matches.
(5) Coal-gas (Bunsen flame).
(6) Hydrogen flame.
(7) Glowing charcoal.
(8) Glowing coals.

§ 5. The method of experimenting was to place the burning substance in position at the bottom of the funnel, to insulate the quadrant of the electrometer in connection with the electric filter, and to start working the air-pump at the rate of one stroke per three seconds. The time of each experiment was ten minutes (200 strokes of the air-pump). The results obtained are given in the following table. In testing the electrometer

Sensitiveness of the electrometer, 111 *scale divisions per volt.*

	Number of experiments.	Mean deflection in scale divisions of electrometer.	Potential in volts.
(1) One candle	2	90 neg.	0·81 neg.
(2) One paraffin lamp ...			
(*a*) without glass funnel	2	84 ,,	0·76 ,,
(*b*) with glass funnel ...	2	30 ,,	0·27 ,,
(3) One spirit lamp ...	4	109 ,,	0·99 ,,
(4) Four portable electrometer matches ...	2	224 ,,	2·03 ,,
(5) One Bunsen flame ...	4	30 ,,	0·27 ,,
(6) One hydrogen flame	At low pressure gave small negative; at higher pressures large positive. No electrification was found from the jet at any pressure when not burning.		
(7) Charcoal (8) Coals	Both gave negative electrification when there was a flame ; and both gave positive electrification when they were glowing without flame.		

matches, four matches were stuck in holes in a metallic plate, and the plate connected by a wire to the case of the electrometer. These matches, according to a suggestion made more than thirty years ago by Faraday, are made of white blotting-paper soaked in a solution of nitrate of lead, and rolled up with paste into little rods of about five millimetres diameter. The hydrogen was generated in an ordinary Woulfe's bottle from zinc and hydrochloric acid. The rise of the dilute hydrochloric acid in the long vertical tube through which the acid was admitted, indicated the pressure under the nozzle, above which the hydrogen was burning.

§ 6. In the case of the charcoal and coal, the burning fuel was placed at the bottom of the iron funnel in a thin rectangular metallic vessel with small holes perforated in the bottom and in the sides. A wire from the case of the electrometer passed through one of these holes, and was thrust into the burning fuel. It was noticed that when the burning charcoal was first put in position below the funnel it always produced negative electrification, which ultimately changed to positive. Thus, in four experiments, the electrification, which was at first negative, became positive after 8, 10, 14, and 18 minutes respectively. On investigation it was found that as long as any flame[1] was visible in the burning charcoal the electrification was negative ;

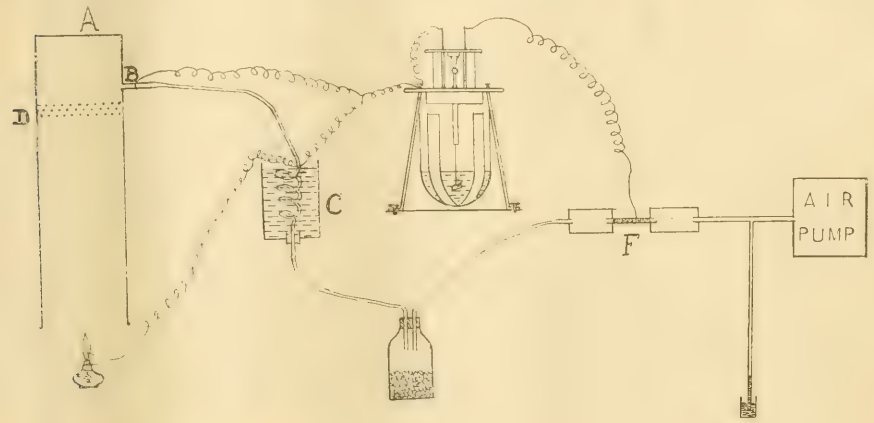

FIG. 1

but as soon as all the flame disappeared, leaving only the red glow, the electrification became positive. To test this the heated

[1] In a paper on "Electrification of Air by Combustion," by Magnus Maclean and Makita Goto, communicated to the Philosophical Society of Glasgow on November 20, 1889, is a statement of results of many observations to find the potential to which the insulated quadrant of a quadrant electrometer is raised when in metallic connection with various kinds of flames and fires. It is there said : "The effect of an ordinary lucifer match is very interesting. While the match is burning with a flame the deflection indicates positive electrification ; but after the flame ceases the electrification becomes negative, the effect now being that of glowing charcoal." The following table is quoted from the paper. In some cases the burnings lasted so short a time that quantitative determinations of the potential were not obtained. It is *conceivable* that all of the complementary opposite electricity separated from that which went to the electrometer in those experiments went to uninsulated solids in the neighbourhood. The experiments described in the text demonstrate that some of it was lodged in the air and fumes proceeding from the fire or flame.

Substances giving flames or burnings.	Electrification of insulated fuel.	Greatest observed potential in volts.

charcoal was kept away from the funnel till all flame had disappeared. Then the vessel was put in position, and the deflections obtained in two experiments were—

51 scale divisions positive in 10 minutes.
100 ,, ,, ,, ,, ,,

§ 7. Next an experiment was made with the burning charcoal put in position while a flame was visible. The flame remained visible for 7 minutes, and in that time a negative electrification of 34 divisions was obtained. Then the deflection came back to the metallic zero in one minute, and in 10 minutes more a

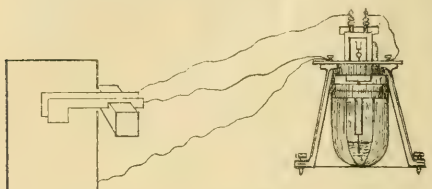

FIG. 2

positive electrification of 87 divisions (0·78 volts) was obtained.

§ 8. Glowing coals taken from the fire and put at once in the vessel in position, repeatedly gave negative electrification; but when they were kept away from the funnel till all flame had disappeared, the electrification obtained was slightly positive. Glowing coals remained glowing a very short time after all flame ceased, and the smallness of the observed effect is probably due to this cause.

§ 9. A few experiments have also been tried to find to what positive potential the flame must be raised so as to overcome the negative electrification it gives to the air. Hitherto the only flame tried was a spirit flame. The positive electrode of a secondary cell was put into the flame of the lamp, and the negative electrode was joined to the iron funnel and to the case of the electrometer. The results obtained are not very regular, but we found that one storage cell was not sufficient to overpower the electrifying effects of the spirit flame. With one cell we got 45 divisions negative in 10 minutes, instead of 109 divisions with metallic connection; with two cells we got 10 divisions positive in 10 minutes; and with six cells we got 83 divisions positive in 4 minutes.

§ 10. The filter, pump, and worm were now removed, and two plates—one of polished copper, and the other of polished zinc—were fixed 0·9 centimetre apart in a block of paraffin, as represented in Fig. 2. The arrangement was such that either plate could be insulated, while the other was kept in metallic connection with the case of the electrometer. Observations were made to find the deflection from metallic zero with one plate insulated, and fumes from different flames and burnings at different distances from the plates passing up between them. This may be called the fumes-zero. When the top of the flame was within 5 or 6 centimetres from the plates, the results were very irregular. The results in the following table for spirit flame are in accordance with what Maclean and Goto obtained from unguarded fumes from a spirit lamp 30 centimetres below the plates, as stated in their paper published in the *Philosophical Magazine* for August 1890. The effect is of the same kind as if the plates were connected by a drop of water.[1]

§ 11. To observe the leakage between two parallel metal plates, the zinc plate was removed, and a polished copper plate, equal and similar to the other copper plate, was substituted for it. The distance between their parallel planes was 0·9 cm. The experiments were conducted as follows: One pair of quadrants of the electrometer, with one of the copper plates in metallic connection with it, was insulated. There was now no deviation from metallic zero. A small charge, positive or negative, was given to it, producing a deflection of about 450 scale divisions. This corresponds to over 9 volts, as the sensitiveness of the electrometer now used was 48·2 scale divisions per volt. In two or three minutes the ordinary leakage of the arrange-

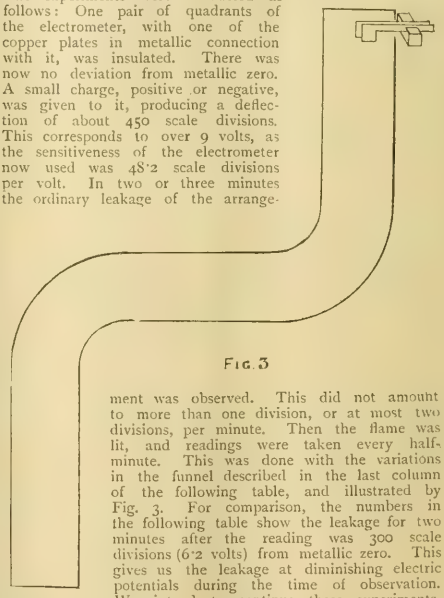

FIG. 3

ment was observed. This did not amount to more than one division, or at most two divisions, per minute. Then the flame was lit, and readings were taken every half-minute. This was done with the variations in the funnel described in the last column of the following table, and illustrated by Fig. 3. For comparison, the numbers in the following table show the leakage for two minutes after the reading was 300 scale divisions (6·2 volts) from metallic zero. This gives us the leakage at diminishing electric potentials during the time of observation. We intend to continue these experiments, and to arrange to find the leakage at different constant electric pressures.

§ 12. The marked difference in the leakage obtained when the horizontal tube was of small bore (3·8 cms.) and when it was of larger bore (15·3 cms.), may be contrasted as indicated in the last four results given for spirit flame. We also tried how long the fumes retained this conductive quality, but in every case we found that the leakage stopped in less than a quarter of a minute after the flame was extinguished, or removed from the bottom of the funnel. Closing the top and bottom of the funnel immediately after the flame was removed, we still found that the

± 300 *scale divisions, equivalent to* 6·2 *volts, to begin with in each case.*

conductive quality of the air and fumes ceased within a quarter of a minute.

§ 13. In connection with these last experiments, attention may be directed to an experiment described by Prof. Schuster, in which he uses an insulated metallic tube bent round at the upper end, to prove that "it is not only the flame itself which conducts, but also the gases rising from the flame."[1] He discovers electric conductance in products of combustion mixed with air quite out of sight from the flame.

SURVEY OF THE TIDES AND CURRENTS IN THE GULF OF ST. LAWRENCE.

WHEN the meeting of the British Association was held at Montreal in 1884, the necessity of establishing stations for tidal observations in Canadian waters was discussed, and the Association adopted a resolution drawing the attention of the Government of the Dominion to the matter. A committee was also appointed to collect information and make representations to the Government respecting it. Two years later a large deputation, representing the British Association, the Royal Society of Canada, and the Board of Trade of Montreal, waited on the Minister of Marine. The matter was favourably received, but, owing to financial reasons, any action was for the time postponed. In 1889, however, exploratory trips were undertaken, by direction of the Government, with the view of ascertaining the best points to establish tide gauges; and in 1890 a practical commencement of the survey of the tides and currents in the Gulf of St. Lawrence was made. The object of this survey is to furnish data for compiling trustworthy tide-tables, and to afford information as to the set of the tidal and other currents in the Gulf. The value of such information is shown by the remarks of Lieut. Gordon in his report to the Minister of Marine, in which he expresses the conviction that until an exhaustive examination of the whole system of tidal movements carried out on similar plans to those which have been made on the United States coasts, and on the coasts of Great Britain, has been made, there will always be the liability to heavy maritime losses due to the lack of information. The average loss, he states, is now over half a million of pounds—a large proportion of which is due to a want of knowledge of the currents.

For the purpose of determining the set and cause of the currents, it was necessary to have a trustworthy record of the time and range of the tides; of the variation in the pressure of the barometer; the force and direction of the wind; and the temperature and density of the water at different depths. The survey is under the charge of the Marine Department, with Colonel Anderson, Chief Engineer, at the head. The tidal survey is in charge of Mr. W. Bell Dawson, C.E. Four reports as to the progress of the work have already been issued. In the first season the two entrances to the Gulf were examined at Belle Isle and Cabot Straits, between Cape Breton and Newfoundland; and the general relation of the Gulf to the ocean as regards tide and currents was examined. Next season the entrance between the Gaspé coast and Anticosti was examined, and the nature of the currents was traced across the south-western side of the Gulf to Cape Breton. This part of the Gulf is a steamship route of constantly increasing importance. More recently, the north-eastern arm of the Gulf, from Anticosti to Belle Isle, through which passes all the Atlantic traffic which takes the Belle Isle route, has been under examination. Seven self-recording tide gauges have also been set up, the establishment of the intended stations on the Atlantic coast having been postponed owing to the want of funds. Although the shortest time for obtaining a correct computation of the tides at any port is the lunar cycle of nineteen years, sufficient data have been collected to enable the Department to issue tide-tables for the use of the pilots of the St. Lawrence, and for Halifax.

It has been settled that the current in the Strait of Belle Isle is fundamentally tidal; and, under normal conditions, runs east and west, with velocities of about two knots in each direction. During heavy winds, especially when westerly, the current which runs with the wind becomes stronger than the current against it; and for a time the current may become continuous in the same direction as the wind.

The tides vary in height from four to five feet in the open Atlantic, to twelve feet in the lower part of the St. Lawrence River, seventeen feet at Quebec, and thirty feet over the Bay of Fundy. To correctly observe these, tide gauges fixed at different parts of the coast are required. Owing to the uninhabited condition of a great part of the coast, the difficulty in selecting suitable places and attending to the gauges has been very great. The self-recording gauges used are of the usual design, but special precautions have had to be taken to guard against the effect of ice and the oscillation due to wave action. At most stations no wharves or quays were available against which the gauges could be fixed. At some of the stations wells had to be sunk at high-water mark to the level of the lowest tides, and a trench, 270 feet long and 10 feet deep, excavated across the rock shore, to admit the tide to the well. The tide was led to the well by wooden piping, made from fir trees, twelve inches diameter, having a hole three inches in diameter bored through the centre, the joints being made tight with sail-cloth saturated with white lead. To prevent the effect of air entering the pipes, due to the surge of the sea in rough weather, an iron pipe was laid out along the bottom for about 100 feet, into water having a depth of twelve feet at the lowest tides. To prevent freezing in winter, a boiler, three feet in diameter, was placed vertically in the well and kept heated, and in this the tide pipes were fixed. These gauges have been occasionally damaged during gales, and in one case the station could not be reached between January and the opening of the navigation in May. At some of the stations, situated on islands, it was necessary to make a telegraphic exchange of time once a week to regulate the driving clocks. To avoid this expense, meridian instruments, named *dipleidoscopes*, have been employed, which, when once set correctly, give the exact time of the sun's meridian passage. These were obtained from a Paris maker.

The currents in the Gulf are affected both by the tide and the amount of fresh water coming down the river. It was found that the under-currents which exist are frequently displaced and brought nearer the surface, either by the effect of wind or by a variation in the temperature. For the purpose of ascertaining the position and force of these currents observations were taken as to their flow, and also as to the temperature and density of the water. From Quebec to Father Point the tidal current occupies the whole width of the river; when the channel widens, a part of it is occupied by a constant downward current which runs parallel to the south shore all the way to Gaspé. The main tidal current enters the Gulf from the Atlantic by Cabot Strait, between Cape Breton and Newfoundland, and does not lose itself in the great expanse of the Gulf, but continues across

[1] Prof. Schuster, on "Atmospheric Electricity," at Royal Institution, February 22, 1895.

it with an increased range in the passage between Gaspé and Anticosti, and from there pursues its way with ever-increasing height up the St. Lawrence to Quebec. The progress of this tidal wave has been traced to the existence of a deep channel which crosses the whole extent of the Gulf from Cabot Strait to the passage between Gaspé and Anticosti, and thence up the St. Lawrence nearly to Saquenay. This channel extends a distance of 500 miles, with an average width of 35 miles and a continuous depth of 150 fathoms.

For the purpose of ascertaining the nature and velocities of the currents, the steamer used was moored with a wire rope hawser, provided with an accumulator, to prevent sudden jerks and strains. This accumulator consisted of a series of sixty rubber discs, five inches diameter, making a total length of twelve feet, which was reduced to eight feet eight inches under the greatest compression. Two kinds of current meters were used: one having small buckets revolving horizontally, on the same principle as an anemometer; and the other of a fan, similar to a screw propeller, revolving in a vertical plane. The former was found to be best for sea work, as it was least affected by the vertical motion of the vessel due to waves. The latter was found to be liable to head up or down as the vessel rolled, and so give an exaggerated record. Both kinds were worked by electricity. The surface currents were taken at a uniform depth of eighteen feet, which was well clear of the keel of the steamer. The meter was allowed to run for half an hour at this depth, then lowered to the desired depth for an hour, and then again run for half an hour at the eighteen feet. At a depth of ten fathoms the Gaspé current was sometimes found to be stronger than at the surface, but usually the velocity decreased regularly with the depth. At twenty fathoms it was only 50 per cent. of the surface velocity; and at thirty fathoms, 20 per cent. The greatest velocity was 2·81 knots. The current fluctuated with the rise and fall of the tide, decreasing during the rise, and increasing during the fall. The constant outward current from the Gulf was found to have a width of fourteen miles, and a depth of forty fathoms near the Gaspé coast, with a surface velocity of from 1·10 to 2·81 knots. The temperature in July was found to range from 53° at the surface to 33° at thirty fathoms; and 32° at fifty fathoms. In the Gaspé region and in Cabot Strait the coldest water forms a layer between the depth of thirty and fifty fathoms, and, while the surface water rises in temperature during the season, no appreciable variation was found from June to September at a depth of fifty fathoms.

The density of the water was ascertained as affording an indication of the quantity of fresh water coming down the St. Lawrence. In the Strait of Belle Isle and Cabot Strait the density of the surface water ranges from 1·0233 to 1·0245, the same as in the Atlantic. On the western side of Cabot Strait, the outflowing water, which occupies a width of about ten miles, has a density of 1·0220 to 1·0235 at the surface. In the Gaspé region the average density for a width of fourteen miles, and between the surface and ten fathoms, was 1·02195: and to a depth of forty fathoms, was 1·02368. The density of the water is disturbed by currents due to wind. Thus during three days, when the wind from the S.S.W. averaged twenty miles an hour, the density contours were displaced to the northward about nineteen miles at the surface, fifteen miles at ten fathoms, and nine miles at twenty fathoms.

The completion of the survey is expected to occupy another three or four years.

AGRICULTURAL EXPERIMENTS IN PLOTS AND POTS.

IN a recent number of the *Agricultural Gazette of New South Wales* (vol. vii. p. 663) there is an article by Mr. N. A. Cobb, written at the request of the Minister for Agriculture, upon the methods employed for experiments with crops and manures. It appears that field experiments are being carried out to a considerable extent by the farmers of the country, but that the results are to a large extent untrustworthy and misleading, owing to innumerable sources of error which the experimenters have failed to perceive and guard against. Science is thus brought into ill repute, doubt is thrown on established truths, and progress hindered. The evidence brought forward goes far to show that this is a true indictment. When, however, the author goes a step further, and speaks of field experiments as almost essentially untrustworthy, we cannot agree with him. The sources of error which he mentions may all be avoided by judicious management, if only the experimenter will guard against them at the commencement of his work, and superintend his operations with proper care.

Inequalities of soil are one of the worst evils in field experiments; the investigator frequently remains unconscious of them, the difference in the results being credited to the effect of the manures, &c. It is *very rare* for proper precautions to be taken against this evil, for the simple reason that these precautions imply delay, and the experimenter is generally in a hurry to obtain results. If, for instance, the comparative effect of different manures on barley is to be ascertained, or the comparative yield of different varieties of seed, the only basis for an accurate trial is to divide the field into the required plots, then sow the whole field with a uniform barley seed, without any manure, and weigh separately the produce of each plot. If the crops obtained are equal, within the unavoidable errors of experiment, the field is one suitable for the purpose of the experiment; if the crops are unequal, the field, or that portion of it in which the inequality occurs, is clearly unsuited for the purpose intended. It is not sufficient, as is often supposed, to inspect the field when under ordinary culture, and because of the apparent evenness of the crop, to pronounce it fit for use; for natural inequalities of soil may not appear in a well-manured field, although plainly manifested when the supply of manure ceases.

The errors due to inequalities of the soil in one series of trials may, of course, be neutralised by making many series of trials, and substantial accuracy may be gained by simply regarding the mean results obtained; but if a field is really unequal in fertility, no ordinary arrangement of duplicate plots will suffice to ensure an accurate result. If the same experiment is repeated throughout a wide district, as is often now done in County Council experiments, it may be quite misleading to take the mean of all the results as expressing the truth for the whole district. We must not bring into the mean the results obtained in different soils and climates, unless, indeed, our aim is to procure general statistics which are of no value for any particular place. Basic slag and superphosphate will compare quite differently upon a clay and upon a chalky soil; nitrate of soda and sulphate of ammonia will compare differently on dry and wet soils. To take the mean of experiments made under such different conditions is simply to misinform every farmer in the district; yet public money is continually wasted in this way.

Mr. Cobb points out that the effect of inequality in the soil may be obviated by substituting rows for square plots. This is true, and the point is well worthy of attention; the suggestion is not, however, novel. In a comparison of basic slag and superphosphate for turnips, conducted by the writer at Rothamsted in 1886, the slag and turnip seed were sown by drill on the top of two ridges down the whole length of the field, and on the return of the drill an equal number of ridges by the side of the first were left unsown. When the sowing of the slag was completed, the same drill sowed superphosphate and turnip seed in all the vacant spaces. There were thus throughout the field two rows of turnips with slag, side by side of two rows of turnips with superphosphate, the repetition occurring many times over. This plan was suggested by Sir John Lawes. This is, for many experiments, a good mode of work, but its use is practically limited to those crops and manures which can be sown by drill; unfortunately, drills are not satisfactory machines for evenly distributing given weights of manure over given areas.

Mr. Cobb next passes to the pot system of experiment: he describes the work at the Darmstadt Experiment Station, with its 1000 pots, and suggests that work on this system should be commenced in Australia.

There is no doubt that for solving certain questions the pot system, when carried out with scrupulous accuracy, is far superior to any other. If we wish to know what is the comparative value to any plant of various nitrogenous manures under the most favourable conditions of supply and use, we arrive at this fact only by pot experiments. The produce obtained per unit of nitrogen in the pot will not, however, necessarily be the produce obtained in the field; and the relative value of different manures, as shown in the pot, will only by mere chance appear in the field, where, in fact, it will be found to vary every year. The essential difference between the two systems is due to the fact that the field results are largely influenced by the season, and especially by the amount of rain, and the quantity of water percolating through the soil; while the pot cultures are carefully protected from such vicissitudes. If, then, the farmer

wants to know how nitrate of soda, sulphate of ammonia, and shoddy, compare in his own land and climate, the only way of ascertaining the fact is by field experiments repeated through many years, till the influence of an average season is ascertained.

R. W.

COLLIERY EXPLOSIONS AND COAL-DUST.

AT a meeting of the Physical and Chemical Section of the Bristol Naturalist Society, on January 26, a paper was read, by Mr. Donald M. D. Stuart, upon "The Chemistry of Colliery Explosions due to Gases derived from Coal-dust," in which the researches of Faraday, Verpilleux, Vital, Marreco, Mallard, Le Chatelier, and others were given, and attention was drawn to the points they emphasised. Faraday observed in his report upon the Haswell Colliery explosion: "There is every reason to believe that much coal-gas was made from the coal-dust in the very air itself, by the flame of the fire-damp; . . . and that much of the carbon in this dust remained unburnt only for want of oxygen." M. Vital concluded that—"Very fine coal-dust rich in inflammable constituents, will take fire when raised by an explosion, and that portions are successfully decomposed, yielding explosive mixtures with air, whereby the fire is carried along." Marreco remarked—"The coal-dust is in part submitted to destructive distillation"; and Mallard and Le Chatelier found that gaseous matters were evolved from the coal-dust by the action of the fire-damp explosion. Mr. Stuart observed. These physicists and chemists found that the coal-dust did undergo dry distillation while in atmospheric suspension in a mine passage, after the originating explosion; and the educts added to the explosive effects. He had carefully observed the effects of explosions not only at the point of origin, but throughout the field of the disturbances, and found Faraday's hypothesis of the dry distillation of coal-dust essential to account for the phenomena observed through thousands of yards of mine passages. He observed that the disruptive effects of an explosion of methane and air were necessarily limited to the immediate vicinity of the explosive mixture; but the disruptions beyond and to remote distances required an explosive agent coextensive in distribution, and this agent was coal-dust.

The fields of disturbance exhibited the effects of gas-explosion at separate points of space, with intervals of no explosion but of heat, partial combustion, and dissociation; requiring, for explanation, a chain of chemical changes liberating quantities of heat, and accumulating an explosive mixture at the place of explosion. The question arose whether a given volume of air could hold in suspension, as dust, a sufficient weight of coal to give, by its resolution into gas, more gas than the given volume of air was capable of burning or exploding; and investigation showed that the coal yielded a quantity of combustible gases, not less than one half the volume of the air in which it was suspended. In these conditions there could be only partial combustion, until a place was reached where the mine passage emerged into a capacious chamber in which the unconsumed gas found sufficient atmospheric oxygen, and was exploded by the flame in the partial combustion referred to. The disruptive effects were located in places of large air capacity in the paths of coal-dust.

At the point of origin, the coal-dust was reduced to coke, the residue of dry distillation; and this phenomenon was of frequent recurrence in the paths of the propagated explosions. Amorphous carbon was found universally deposited in the field of explosions, chiefly upon the vertical side-walls; it was also in copious suspension in the stagnant atmosphere in the passages, and the effluent gases at the shafts. Combustible bodies, as timber, cotton fabrics, and candles, forming obstructions in the paths of coal-dust and between the explosions, were not consumed or burned. The bodies of the victims in these intervals were blistered to various degrees; the cotton fabrics retained their external form, but had been deprived of their volatile matter, the candles had melted and run together, and the adjacent coal-dust and lumps of coal had undergone dry distillation. These effects upon the coal, men, calico, and candles disclose the fact that the atmospheric oxygen in the mine passages was not more than adequate to supply a portion of the educts of the coal undergoing distillation; consequently there was no oxygen available for the chemical requirements of other combustible bodies, as timber, clothes, cotton fabrics, and candles.

The chemical changes in the intervals from explosion to explosion caused considerable diminution in the atmospheric pressure, indicating a very small production of permanent gases, and the employment of the atmospheric oxygen to form readily condensible gas.

The explosions at the non-gaseous Camerton and Timsbury Collieries were originated by the heat in the products of the exploded blasting powder. The temperature of fired powder of a similar composition was determined by Abel and Noble at 1800° to 2000° C.; the products, therefore, struck the coal-dust in the immediate vicinity while at an exalted temperature, certainly higher than that of the gas retort, which is below 1000° C. The educts of the coal-dust would consequently be similar to ordinary illuminating gas. The composition of London gas is given (by Frankland) at 51·24 per cent. free hydrogen, 38·84 per cent. gaseous hydrocarbons, and some other bodies.

Upon the foregoing and other data, Mr. Stuart advanced the following rationale of a colliery explosion:—The educts of the coal are in excess of the relative combination volumes of atmospheric oxygen present; therefore the large proportion of nascent free hydrogen present, seizes the principal part of the oxygen, liberating heat in the combination. Some of the hydrocarbons obtain the remaining oxygen, causing a limited combustion, as in the preparation of diamond black, disengaging more heat, and placing amorphous carbon in suspension. At the temperature of burning hydrogen, the hydrocarbons that have not undergone change, for want of oxygen, are dissociated, placing more amorphous carbon in suspension, and yielding free hydrogen for disruptive effects.

The heat in the products of the exploded powder, therefore, instituted a series of chemical actions in the coal-dust, in which large quantities of heat were disengaged, and free hydrogen placed at disposal for disruptive action. This series is regenerative by virtue of the heat liberated, which instituted a similar series in the adjacent coal-dust; and these activities are of constant and similar reproduction along the paths of coal-dust until a place is reached, which supplies a large quantity of atmospheric oxygen, in which the accumulated hydrogen diffuses, and the mixture is ignited by the flame in the partial combustion, causing an explosion. This explosion liberates more heat, and re-establishes a similar chain of chemical changes in the coal-dust beyond, closing in a second explosion at the next abnormal supply of air, and propagation proceeds along each path of coal-dust so long as adequate oxygen is available, and wet surfaces do not intervene to reduce the temperature below the point at which the coal undergoing distillation yields sufficient free hydrogen to supply by its oxidation enough heat to make the actions continuous. The paper was illustrated with limelight slides, and was followed by an interesting discussion. Upon the motion of the President, Mr. Stuart was cordially thanked for his paper.

A NEW DIPHTHERIA ANTITOXIN.

A RECENT number of the *Archives des Sciences Biologiques*, issued by the Imperial Institute of Experimental Medicine in St. Petersburg, contains a highly important communication from Dr. Smirnow, on a new method of obtaining a diphtheria antitoxin of great therapeutic value. For the last three years Dr. Smirnow has been working on this subject, and the present memoir places experiments, which before were only in a tentative stage, on what now appears to be a sound and practical basis.

As is well known, the preparation of curative diphtheria serum involves not only great expense, but also a great deal of time; the raising of a horse's serum to the requisite pitch of immunising properties requiring many weeks. Dr. Smirnow has been endeavouring to produce an antitoxin, the preparation of which is less costly and less cumbersome. The method adopted was that of electrolysis, and in the first instance ordinary serum was electrolysed; but as this led to nothing, virulent diphtheria broth cultures were substituted for serum, and the results obtained were highly encouraging. These electrolysed cultures were found to contain an antitoxin of great efficacy, and, even when employed in smaller quantities than the therapeutic serum, it entirely protected animals from the effects of diphtheria poison. "Le traitement par cette antitoxine marche d'une manière remarquablement satisfaisante: malgré les périodes les plus avancées de la maladie, il suffit d'un demi

ou d'un centimètre cube pour que l'animal supporte sa maladie même sans grande élévation de température et presque sans aucune réaction à l'endroit de l'infection." So writes Dr. Smirnow; and, indeed, the experiments which he cites with this antitoxin fully justify this favourable verdict. Still more recently it has been employed on dogs, which of all animals are perhaps the most susceptible to diphtheria poison; this being proved by the difficulty which is experienced in immunising them for the production of curative serum. Dr. Smirnow states that a dog weighing from eighteen to twenty pounds, inoculated subcutaneously with 0·5 c.c. of virulent diphtheria broth cultures, usually dies in two or two and a half days after it has been infected. The protective treatment of a purposely infected dog was commenced one day after inoculation, and from 3 to 5 c.c. of the electrolytic antitoxin sufficed to save the animal's life. This quantity Dr. Smirnow thinks might probably be lessened, and yet not interfere with its remedial action. For the technical details of the methods recommended by Dr. Smirnow for the production of this artificial antitoxin, we must refer the reader to the original memoir, to be found in vol. iv. No. 5, 1896, of the Petersburg *Archives* already mentioned. It would appear that in itself the antitoxin is quite harmless, for ordinary guinea-pigs can stand with impunity a dose ten times and more as strong as that required for remedial purposes. As regards the effective quantity for injection, it appears that in the initial stages of the disease there is no difference in the amount required of the serum and Smirnow-antitoxin respectively; but as the disease progresses, whilst yielding to reduced doses of the artificial antitoxin, it will not to similarly reduced doses of antitoxic serum. Its preparation is incomparably simpler, and with a good supply of toxic diphtheria broth in hand, the antitoxin can be produced in a day, whilst, involving far less expense, it can be supplied at a much more reasonable rate. Dr. Smirnow has at least shown that the preparation of a specific remedy against diphtheria is not the exclusive monopoly of the animal organism, but can be elaborated artificially without the assistance of living mechanism. The author is to be congratulated upon the highly successful results which he has so far achieved; and if the therapeutic value of this electrolytic antitoxin is shown to be as great for man as it has undoubtedly proved itself to be for animals, then indeed Dr. Smirnow has made a distinct and important step forward in the domain of preventive medicine.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

THE following are among recent appointments:—Dr. Vélain to occupy the chair of physical geography recently founded in the Paris University; Mr. H. M. Paul and Mr. G. A. Hill to be professors of mathematics in the U.S. Navy.

THE Spanish Universities and other educational institutions under State control have just been thrown open to foreigners by Royal decree. By the new ordinance foreigners are admitted to the right of matriculation, study, and examination in all educational establishments under the Spanish Government, and are entitled to take degrees in the Universities.

IT is reported (says *Science*) that the subsidy given by the state to the University of California will be doubled, being hereafter 240,000 dols. annually. Mr. Levi Strauss, of San Francisco, has endowed twenty-eight undergraduate scholarships in the University, and seven graduate scholarships, of the value of 250 dols., have been endowed by other donors. The number of students in the University has increased from 918 in 1891–2 to 2250 in the present year. It is again stated that the University will receive gifts amounting to 5,000,000 dols. for buildings, of which sum 1,200,000 dols. is promised by Mrs. Hearst, of San Francisco. Chicago University has received a gift of 225,000 dols. from Mrs. Mary Esther Reynolds, in fulfilment of a pledge made nearly five years ago.

SCIENTIFIC SERIALS.

Symons's Monthly Meteorological Magazine, April.—The first daily weather map. In September 1895, Mr. Symons issued a photographic reproduction of the first daily weather map ever published, and promised to give its history, after making further inquiries. In 1849 the proprietors of the *Daily News* decided upon publishing reports of wind and weather. The organisation was entrusted to Mr. Glaisher, who travelled over the country, and, with the co-operation of the railway and electric telegraph companies, erected instruments and instructed the clerks in their use. The issue of the above journal for June 14, 1849, contained the earliest known telegraphic weather report. During the Exhibition of 1851, the Secretary of the Society of Arts decided upon issuing the information collected by the Electric Telegraph Company in the form of a daily weather map, the first of which appeared on August 8, 1851.—Scientific kite work in the Arctic regions. In a foot-note to Dr. Harvey's article on meteorology, in the *Encyclopedia Metropolitana*, there is a description of an experiment made by the Rev. G. Fisher and Captain Sir E. Parry, at the island of Igloolik, in lat. 69° 21′ N. and long. 81° 42′ W. during the winter 1822–23. The height observed was 379 feet, and the temperature recorded was −24°, there being no variation in the temperature between that altitude and the surface of the earth, although the thermometer was capable of indicating the smallest change.

SOCIETIES AND ACADEMIES.

LONDON.

Linnean Society, April 1.—Dr. A. Günther, F.R.S., President, in the chair.—Mr. Miller Christy exhibited three royal state cloaks formerly worn by the kings of the Hawaiian Islands, and made of the feathers of four species of birds, of which the exhibitor gave an account, referring to the coloured figures of them given in Mr. Scott Wilson's "Birds of Hawaii," namely, *Vestiaria coccinea* (red), *Psittacirostra psittacea* (green), *Acrulocercus nobilis*, and *Drepanis pacifica* (black and yellow). The last-named, of which no specimen is to be found in the National Collection, was believed to be now extinct.—Mr. W. T. Thiselton-Dyer exhibited: (1) A series of drawings (on the screen) to illustrate the "Cultural Evolution of *Cyclamen latifolium*, Sibth." The species is a native of Greece and the Levant, and is believed to have been first introduced into European cultivation in 1731. In 1768 Miller described a form modified by cultivation, under the name of *Cyclamen persicum*. This was erroneous, as, according to Boissier, neither the wild nor the garden form occur in Persia. The latter persisted in cultivation for about 150 years, and about 1860 became the starting-point of the modern races which were illustrated. *Cyclamen latifolium* has never been hybridised, and it was shown that the striking forms now in cultivation were the result of the patient accumulation of gradual variations. Drawings of the remarkable forms, "Papilio," obtained by de Langhe-Vervaene, and of the "Bush-Hill Pioneer," by Messrs. Hugh Low and Co., were shown. It was pointed out that the tendency of the species under cultivation was to lose its distinctive generic characters, and to approximate to a more generalised type. The reflexion of the corolla-segments was often lost, as in *Lysimachia*; the segments were sometimes multiplied, as in *Trientalis*; and the margins were fringed, as in *Soldanella* and cultivated forms of *Primula sinensis*. The "Bush-Hill Pioneer" possessed, in the cresting of the petals, a remarkable character, without parallel in any primulaceous plant occurring in a wild state. (2) A series of plants was exhibited to illustrate the origin of the garden "Cineraria." It was generally agreed that this had sprung from one or more species native of the Canaries. An extreme cultivated form was shown, and compared with *Senecio cruentus*, which all internal evidence indicated as the sole original stock. *S. Heritieri*, another reputed parent, was exhibited. But it was pointed out that this has a shrubby habit and stems markedly zigzag between the internodes, while the leaves are clothed beneath with a dense white tomentum. These characters it transmits, more or less, to its hybrid offspring. In illustration of this point, Mr. Poë's hybrid (*S. super-Heritieri* × *cruentus*) was exhibited (a similar one has occurred at Edinburgh); also the Cambridge hybrid (*S. super-cruentus* × *Heritieri*. *S. cruentus* crosses very freely with the garden Cineraria, and as the latter never exhibits any trace of the characters of *S. Heritieri*, it was concluded that that species had no part in its origin, and that, as in the case of the Cyclamen, the striking development of *S. cruentus* in cultivation was due to the continued accumulation of gradual variations.—Mr. A. W. Bennett exhibited a series of drawings, by Mr. E. B. Green, of root-hairs of plants with various parasitic growths, and showed

preparations of several under the microscope.—Mr. G. R. Murray exhibited several lantern-slides of coccospheres and rhabdospheres, prepared from specimens collected by Captain Milner, of the ss. *Para*, while on a voyage to Barbados, including all the forms figured in the *Challenger* Report (see p. 510).—Mr. H. Groves exhibited a large number of *Characeæ*, collected by Mr. T. B. Blow in various parts of Australasia and Asia, views of the localities referred to being shown on the screen by the collector.—Mr. George Massee, on behalf of Miss Helen B. Potter, communicated the substance of a paper on the germination of spores of *Agaricineæ*.—A paper by Dr. A. J. Ewart, on the evolution of oxygen from coloured bacteria, was deferred for reading until May 6 next.

Entomological Society, April 7.—Mr. Roland Trimen, F.R.S., President, in the chair.—A memorandum of an association for the protection of insects in danger of extermination, which had been drawn up by a Committee appointed for the purpose and approved by the Council, was laid before the Society and signed generally by those present (see p. 588).—The draft of alterations and additions to the Society's bye-laws, recommended for adoption by the Council, was read for the first time.—Mr. McLachlan showed, on behalf of Mr. Gerald Strickland, a magnified photograph of *Brachycerus apterus*, obtained by direct enlargement in the camera, and extremely clear in definition and detail.—Mr. Tutt exhibited some of the silk used by *Tephrosia bistorta* to cover its ova, and discovered by Dr. Riding. It was contained in a pouch at the extremity of the abdomen in the form of dense bundles about 2 mm. long, and resembling in miniature locks of wavy flaxen hair. Hitherto all such coverings were supposed to consist of scales from the anal segment.—Papers were communicated by Prof. Miall, F.R.S., on the structure and life-history of *Limnobia replicata*, and by Messrs. Godman, F.R.S., and Salvin, F.R.S., on new species of Central and South American Rhopalocera.

Mathematical Society, April 8.—Prof. Elliott, F.R.S., President, in the chair.—The President made some appreciative remarks upon the late Prof. Sylvester, dwelling more especially upon the loss to the Society and to the mathematical world generally sustained by his death. He mentioned that he had been authorised by the Council to write a message of sympathy to the deceased Professor's nearest relative.—The Rev. F. H. Jackson read a paper on the extension of a certain theorem (connected with Gauss's hypergeometric series).—Mr. Macaulay gave a sketch of a note on the deformation of a closed polygon, so that a certain function remains constant.—Mr. Love communicated an abstract of a paper, by Prof. Sampson, entitled "A Continuation of Gauss's Dioptrische Untersuchungen."—The President communicated from the chair a paper, by Herr Sommerfeld, "Ueber verzweigte Potentiale im Raum." (The method of the paper is a generalisation of Lord Kelvin's theory of images, and there are in it some interesting applications to diffraction problems. The paper was presented at the instance of Prof. Klein, who would like to bring about a somewhat livelier connection between English and German mathematicians.)—Mr. S. Roberts, a past President of the Society, having taken the chair, Prof. Elliott communicated papers, by Mr. A. L. Dixon, on the potentials of rings, and by Mr. J. W. Russell, on certain concomitant determinants.—Mr. R. Hargreaves and Lieut.-Colonel Cunningham, R.E., made impromptu communications, the latter writing on the board the following high primes:—305, 175, 781; 466, 344, 409; 550, 554, 229; 632, 133, 361.

EDINBURGH.

Royal Society, April 5.—Prof. McKendrick, in the chair.—A paper by Lord Kelvin and Dr. Maclean, on the electric properties of fumes proceeding from flames and burning charcoal (p. 592).—The automorphic linear transformation of a quadric, by Dr. Muir.—On ethene prepared from ethyl-iodide, and on the properties of some mixtures of ethene and butene, by Prof. Kuenen.—Continuation of experiments on electric properties of uranium, by Lord Kelvin and others.—Prof. Tait, in a short communication on the relations among the quantities p, v, t, in a substance, discussed certain of Amagat's recent results in their bearing upon Van der Waal's theory. What at first sight seemed to be a remarkable concordance between this theory and the facts of experiment, proved on closer inquiry to be quite the reverse.—Dr. D. Fraser Harris gave a demonstration of the reducing power of the living animal tissues (cat and rabbit), made by injecting into left external jugular the gelatine and Berlin-blue mixture used for blood-vascular injections. Injection commenced as soon as the animal ceased to breathe, and it was found that the liver most vigorously, and kidney next, reduced the ferric ferrocyanide in the blood-vessels to the pale-green or almost colourless ferrous ferrocyanide, which, on the organs being cut up and exposed to air, was reoxidised to the deep blue ferric salt. This reduction is the expression of the inspiratory phase of the internal respiration, and is a measure of the metabolic power of the living tissues.—In a second paper on hæmatoporphyrinuria and its relations to the source of urobilin, Dr. Harris showed that urobilin—for which urochrome would be a better term, as connoting no particular source of the urinary pigment—cannot now be held to be derived from absorption of altered bile pigment in the intestines. It has a *hepatic*, but not a biliary origin, and in health is formed in the liver probably thus: Hæmatin is there decomposed with deposit of iron and a precursor of urobilin produced, probably the chromogen, which, on traversing the lungs, is oxidised to urobilin, and in the kidneys again partly reduced to chromogen, so that we find both urobilin and its chromogen in the urine. In hæmatoporphyrinuria the urine is orange-coloured, and contains a less deoxidised pigment than urobilin, probably from depraved metabolism in muscular, cutaneous, and connective-tissue systems.—Dr. Albert A. Gray, Glasgow, in a paper on the perception of the direction and distance of sound, dealt, first, with some experiments on the degree of accuracy with which the direction of sound may be estimated. The question of how far the difference of phase with which a sound affects the two ears simultaneously may aid in judging its direction was considered, and Prof. Sylvanus Thompson's discoveries in this connection commented upon. The author described some experiments of his own upon the tympanic membrane, which showed that pressure of the chain of ossicles of one ear inwards caused the opposite ear to hear a sound more loudly. This peculiar fact was shown to be due, in all probability, to a reflex starting from the labyrinth of the first ear, and passing to the *tensor tympani* or *stapedius*, or (more probably) both these muscles of the opposite ear near which the sound was produced. Thus the muscular system of one ear is in connection with the opposite ear, and *vice versa*. As the positive phase of a sound-wave will relax the *tensor tympani*, and render the *stapedius* tense, and the negative phase will produce the reverse effect, it is evident that by means of the muscular sense we may be able to estimate the phase of a sound-wave in each ear, and by comparing both, be able to localise roughly the direction of the source of a sound.—Mr. A. Rankin read a note on the number of gales observed at Ben Nevis Observatory.

PARIS.

Academy of Sciences, April 12.—M. A. Chatin in the chair.—The election of M. Radau as a member in the Section of Astronomy, in the place of the late M. Tisserand, was approved by the President of the Republic.—On the observatory of Mount Etna, after observations of M. Riccò, by M. H. Faye. The observatory is situated about a kilometre from the central crater, at a height of 9650 feet. The chief difficulties have not been due to the eruptions of the volcano, but to the heavy snowfalls, which frequently attain a depth of from seven to sixteen feet at the observatory. The mean temperature for the year is 0°·4 C.—On the law of the discharge in air of electrified uranium, by M. Henri Becquerel. The loss of electricity by uranium appears to be solely effected by the gas in contact with the metal, since the losses sustained by a uranium ball in a vacuum are extremely small, and are of the order of the amounts which would leak through the supports. Reserving the effects of varying the gas for a future communication, the present paper contains the relations experimentally found to exist between the loss of potential and the time.—Further remarks on the classification of the Inseminæ, by M. Ph. van Tieghem.—Morphology of the sternum and clavicles, by M. Armand Sabatier. By a study of the sternum of the crocodile, new light is thrown upon the vexed question of the morphological signification of the sternal apparatus of vertebrates.—Interpretation of the parts of the anther, with special reference to the ovule in the genus *Lépidoceras*, by M. D. Clos.—Some remarks on two recent papers of M. van Tieghem.—Committees were nominated to act as judges for the prizes bearing the names of Philipeaux (experimental physiology), Montyon (unhealthy trades), Cuvier, Trémont, Gegner, Petit-d'Ormoy (mathematical sciences and natural sciences), Tchihatchef, Gaston Planté

Cahours, and Saintour.—Discussion of the barometric heights in the zone 10°—30° N. during 1883, by M. A. Poincaré.—An internal governor for an aerial boat, by M. F. Lacerer.—Photography of Kœnig's flames, by M. Marage.—Experiments made on a new kathodic apparatus, by MM. Foveau de Courmelles and G. Seguy. The apparatus consists of two vacuum tubes joined to a spherical reservoir. The observations with this form show that the interior pressure in a vacuum tube is not equal at all points, this unequal distribution of the gas being produced during the passage of the current.—On the local attractions observed in Fergana, by M. Venukoff.—Heat of formation of formaldehyde, gaseous and dissolved, by M. Marcel Delépine.—On the formation of ammonium cyanide and its manufacture, by M. Denis Lance. Ammonia gas passed over carbon at a temperature of about 1000° C. always gives ammonium cyanide, the yield being greatest when the ammonia is mixed with a considerable proportion of nitrogen and hydrogen, and when the temperature is 1100° C.—Classification of the Orthoptera according to the characters drawn from their digestive apparatus, by M. L. Bordas.—Researches on the histology of the nerve cell, with some physiological considerations, by M. G. Marinesco.—On the physiological and pathological action of the X-rays, by M. Sorel. An account of the serious resnlts following the application of the X-rays to the stomach. It is regarded as inadvisable, at least in certain subjects, to apply the X-rays in the neighbourhood of important organs, such as the stomach, heart, or lungs. It has been remarked that the body of an animal which has been dead for some time is always more opaque to the Röntgen rays than one just dead and still warm.—Remarks on the preceding note, by M. Lannelongue.—On the toxicity of the alcohols, by M. Picaud. A study of the action of the alcohols upon fishes (*Carassius auratus*), batrachians (*Triton vulgaris*), and birds (*Carduelis elegans*). The toxic effect, as with the mammalia, was found to increase with the molecular weight.—Animal evolution, a function of the cooling of the globe, by M. R. Quinton.—Method of vaccination against poisoning by ricin, by M. Ch. Cornevin.—The destination of the megalithic monuments, by M. Ch. Godey.—A hydro-pneumatic motor, by M. G. Housset.—A horizontal barometer with rarefied air without the use of ice, by M. Victor Ducla.

DIARY OF SOCIETIES.

THURSDAY, APRIL 22.

INSTITUTION OF ELECTRICAL ENGINEERS, at 8.—Recent Developments in Electric Traction Appliances: A. K. Baylor. (Continuation of Discussion)

CAMERA CLUB, at 8.15.—Peeps into Nature's Secrets: R. Kearton.

SATURDAY, APRIL 24.

ROYAL BOTANIC SOCIETY, at 4.

TUESDAY, APRIL 27.

ROYAL INSTITUTION, at 3.—Volcanoes: Dr. Tempest Anderson.

SOCIETY OF ARTS, at 8.—Delft Ware: Dr. J. W. L. Glaisher, F.R.S.

INSTITUTION OF CIVIL ENGINEERS, at 8.—Annual General Meeting.

ROYAL STATISTICAL SOCIETY, at 5.30.

ROYAL HORTICULTURAL SOCIETY, at 1.—Winter and Spring Bedding.

ROYAL PHOTOGRAPHIC SOCIETY.—Technical Meeting, at 8.—A Practical Demonstration of Glass-blowing at the Lamp: T. Bolas.

ROYAL VICTORIA HALL, at 8.30.—The Life of an Egg: Dr. W. B. Benham.

WEDNESDAY, APRIL 28.

SOCIETY OF ARTS, at 8.—Asbestos and Asbestic: with some Account of the Recent Discovery of the latter at Danville, in Lower Canada: Robert H. Jones.

GEOLOGICAL SOCIETY, at 8.—On the Origin of some of the Gneisses of Anglesey: Dr. Charles Callaway.—Note on a Portion of the Nubian Desert South-east of Korosko: Captain H. G. Lyons, R.E., Miss C. A. Raisin, and Miss E. Aston

BRITISH ASTRONOMICAL ASSOCIATION, at 5.

THURSDAY, APRIL 29

ZOOLOGICAL SOCIETY, at 4.—Annual Meeting.

CHEMICAL SOCIETY, at 8.—Monochlordipyraconic Acid and some Condensations: Dr. H. C. Myers.—On the Decomposition of Iron Pyrites: W. A. Caldecott.

CAMERA CLUB, at 8.15.—The Automatic Telephone: S. B. Apostoloff.

FRIDAY, APRIL 30.

ROYAL INSTITUTION, at 9.—Kathode Rays: Prof. J. J. Thomson, F.R.S.

EPIDEMIOLOGICAL SOCIETY, at 8.—Some Observations on the Infectivity of Diphtheria, and its Relation to School Closure: Dr. Louis Parkes.

SATURDAY, MAY 1.

ROYAL INSTITUTION, at 3.—Annual Meeting.

GEOLOGISTS' ASSOCIATION.—Excursion to Cookham. Leave Paddington 1.40 p.m.; arrive Cookham 2.30 p.m. Director: Ll. Treacher.

LONDON GEOLOGICAL FIELD CLASS.—Excursion to Leith Hill. Lower Greensand. Leave London Bridge, 2; arrive Holmwood, 3.17.

BOOKS, PAMPHLETS, and SERIALS RECEIVED.

BOOKS.—Le Four Électrique: H. Moissan (Paris, Steinheil).—Meteorology in Mysore, 1895: J. Cook (Bangalore).—A System of Medicine: edited by Dr. T. C. Allbutt, Vol. 2 (Macmillan).—Farm and Garden Insects: Dr. W. Somerville (Macmillan).—Collected Contributions on Digestion and Diet: Sir W. Roberts, 2nd edition (Smith).—Das Studium der Technischen Chemie: Dr. F. Fischer (Braunschweig, Vieweg).—L'Ottica delle Oscillazioni Elettriche: Prof. A. Righi (Bologna, N. Zanichelli).—Some Unrecognised Laws of Nature: I. Singer and L. H. Berens (Murray).—The Ancient Volcanoes of Great Britain: Sir. A. Geikie (Macmillan).—Aids to the Study of Bacteriology: T. H. Pearmain and C. G. Moor (Baillière).—Geology of North-East Durham: D. Woolacott (Sunderland, Hills).—Proceedings of the London Mathematical Society, Vol. xxvii. (Hodgson).—Contributions to the Science of Mythology: Prof. F. Max Müller, 2 Vols. (Longmans).—A Guide to the Fossil Invertebrates and Plants in the Department of Geology and Palæontology in the British Museum (Natural History), S.W. (London).—The Law and Practice of Letters Patent for Inventors: Dr. L. Edmunds and Dr. T. M. Stevens, 2nd edition (Stevens).—With the Dutch in the East: Captain W. Cool, translated by E. J. Taylor (Luzac).—The Forcing Book: L. H. Bailey (Macmillan).—The Story of the Mine: C. H. Shinn (Low).—Problems and Questions in Physics: G. P. Matthews and J. Shearer (Macmillan).—Experimental Morphology: Dr. C. B. Davenport, Part 1 (Macmillan).—Cytologische studien aus dem Bonner Botanischen Institut: E. Strasburger and others (Berlin, Borntraeger).—Recherches sur les Origines de l'Egypte: J. De Morgan (Paris, Leroux).

PAMPHLETS.—Comité International des Poids et Mesures. Procès-Verbaux des Séances de 1895 (Paris, Gauthier-Villars).—Comptes rendus des Séances de la Deux Conférence Générale des Poids et Mesures, 1895 (Paris, Gauthier-Villars).—A Protest against the Modern Development of Unmusical Tone: T. C. Lewis (Chiswick Press).—Criticisms on Darwin's, Wallace's, and Häckel's Evolution Theories (Hodgson).—First Annual Report of the New York Zoological Society (New York).

SERIALS.—Bulletin of the American Mathematical Society, March (New York).—Physical Review, Vol. iv. No. 5 (Macmillan). THURSDAY, APRIL 29, 1897.

THE LIFE AND WORK OF CHARLES PRITCHARD.

Charles Pritchard, D.D., F.R.S., F.R.A.S., F.R.G.S., late Savilian Professor of Astronomy in the University of Oxford. Memoirs of his Life. Compiled by his daughter, Ada Pritchard. With an account of his theological work by the Right Rev. the Lord Bishop of Worcester; and of his astronomical work by his successor, Prof. H. H. Turner, F.R.A.S. Pp. viii+322. (London: Seeley & Co., 1897.)

THE mere fact that the name of the late Prof. Pritchard is most widely known in connection with his astronomical researches, is in itself no uncertain sign of the energy and capacity of the man, for, as he himself stated, he did not really begin his astronomical work until he was seventy years of age. There are, however, other sides of his career for which he is little less worthy of grateful remembrance, exhibiting him, as they do, in the light of a pioneer in more than one important movement.

We therefore welcome the present volume, compiled by those who knew him best, giving a brief and interesting account of his life and work, which, it may be remarked, extended over nearly the whole of the century (1808–1893).

In a charming bit of autobiography, Prof. Pritchard tells the story of his schooldays, and of his struggles, ambition, and success as a schoolmaster. So far as one can judge, his early education was of the type then common, save for a short period during which he attended a private school kept by one John Stock, of Poplar, whose methods appear to have been far ahead of his time. The instruction of schoolboys in geometrical drawing, practical surveying, and the use of physical apparatus, was then (1822) no common undertaking, and this practical work seems to have influenced Pritchard very largely. It is at least certain that his mind was first seriously turned towards astronomy by a collection of Ferguson's models and astronomical instruments, which he had the privilege of studying at this "stirring school."

After a brilliant career at Cambridge, he entered a wider field as an educationist. Having been appointed to the mastership of the newly-founded Stockwell Proprietary Grammar School, he expounded his plans at the opening of the school, and only a few years ago he stated that "with the experience of half-a-century superadded, I can say with sincerity that had I now to form a scheme of education for a large school, it would be on the very same lines as those enunciated in my inaugural address." Suffice it to say that the main intention of his methods was the development of the *habit of thinking*, and as a step to its proper cultivation he proposed to introduce a well-furnished laboratory for the serious study of natural phenomena. He therefore claims to have been a successful pioneer in a most important branch of education. The sincerity of his convictions was afterwards proved when his energies were transferred to the Clapham Grammar School, which eventually passed entirely into his own management and proprietorship; not only did he actually establish the proposed laboratories, but he even went so far as to provide a swimming-bath and an observatory. While submitting to the system of examinations, Pritchard remained unconvinced of their utility, and he stated in 1886 that "the time will come when the competitives will be found to be intellectually and educationally suicidal."

Many of the pupils of the Clapham School have since become famous in various walks of life, and, among others, Dr. Bradley, the present Dean of Westminster, speaks of the great originality and success of the master's methods. Sir George Grove, another distinguished pupil, tells us in this volume how "geography became a reality," and the origin of the Palestine Exploration enterprise may be traced to the special attention given to that country at the Clapham School. One of the late Professor's favourite maxims, reiterated during his career as a schoolmaster, was "Whatever you do, do it as well as you can," and his whole life is a witness of his endeavour to act as he preached.

Pritchard's interest in astronomy took no practical turn until he had the means to add an observatory to his school, the most important part of the equipment being a fine transit instrument purchased at the close of the Exhibition of 1851. For private reasons the school was given up in 1862, and the observatory was removed to the new home at Freshwater, Isle of Wight. At this time Pritchard's repute as an amateur astronomer was so well established that he was elected Secretary to the Royal Astronomical Society, and within a few years he occupied the presidential chair. He took a very active part in the proceedings of the Society, and we have it on the authority of Prof. Turner, one of the present Secretaries, that his official connection with the Society has left lasting impressions on the conduct of its affairs.

The comparative retirement of the life at Freshwater ended in 1870, when Pritchard was appointed to the Savilian professorship. As Prof. Turner points out, he received this appointment rather on account of the man he was than for any conspicuous astronomical work which he had previously done, though, as subsequent events proved, he had only lacked the opportunity of doing justice to his observational ability. His association with the Astronomical Society here stood him in good stead, for he had given little evidence of his power except in ways of which the Society alone could take note, and his appointment was largely due to the representations of some of the more prominent Fellows.

The observatory, which was the scene of Pritchard's future triumphs, was at this time a very small one, but the authorities were soon persuaded to provide a 12-inch equatorial, and Dr. De la Rue's gift of his splendid instruments being made about the same time, an entirely new observatory was erected. The possibility thus opened for photographic work induced Pritchard to style the establishment "The New Savilian Observatory for Astronomical Physics at Oxford." As a matter of fact, however, the spectroscope has practically never been used in the observatory, so that in view of the meaning now attached to "astronomical physics," the observatory has lost the right to the name which Pritchard proudly gave it.

Practical instruction in astronomy was never greatly in demand at Oxford, hence nearly the whole strength of the small staff was available for research purposes, and

especially in two directions, as all the world knows, success was complete. By the use of the wedge photometer, Pritchard raised stellar photometry to the dignity of an exact science, and by the employment of photographic methods he investigated the parallaxes of a large number of stars with results which are probably among the most trustworthy ever obtained in this branch of astronomy.

Another epoch in Pritchard's astronomical career commenced with his offer to take part in the work of the international photographic star chart. Such an undertaking, at his advanced age, was characteristic of him; and the fact that he successfully initiated the work, and left everything in order at the time of his death, illustrates the methodical way in which he set about it.

The successful issue of the various undertakings at Oxford was largely due, as Pritchard himself was always anxious should be known, to the zeal of his assistants, Messrs. Plummer and Jenkins, by whom most of the actual observations were made.

Prof. Turner has succeeded in weaving together an admirable account of Pritchard's astronomical work, but it may be remarked that all reference to his connection with the work of the Committee on Solar Physics has been omitted.

A hitherto unpublished account of Pritchard's observations of the total solar eclipse of 1860 is included in Prof. Turner's story, and though these were overshadowed by De la Rue's magnificent photographic results, it is evident that they were carried out with the forethought and skill which marked all his work.

The selection of correspondence between Pritchard and some of his great contemporaries has, on the whole, been judiciously made, and all concerned in the preparation of the memoirs are to be congratulated on the production of a volume which will be prized by all who knew Pritchard, and one which is at the same time of sufficient interest to command the attention of a much wider public.

WATER AND ITS PURIFICATION.

Water and its Purification. By Samuel Rideal, D.Sc. Pp. xii + 292. (London: Crosby Lockwood and Son, 1897.)

THE author of this work describes it on the title-page as "a handbook for the use of local authorities, sanitary officers, and others interested in water supply." It is thus admittedly a book which is designed more for the general reader than for the engineer, the chemist, or the bacteriologist. That this is so we have further evidence in the preface, where we read that—

"The closing of polluted wells, and decisions on new supplies, are now, however, in the hands of the general public, who, and their elected representatives, thus need to become acquainted with the results of the progress made during the last few years in bacteriology and knowledge of the causation of disease."

The book deals with the characters of different kinds of natural water, animal and vegetable impurities, the storage, filtration and distribution of water, the softening and purification of water, and lastly its analysis and the interpretation of results. On reading the book one finds that the author has not been able to refrain from including a large amount of technical detail, which is, however, treated too superficially to be useful to the serious student of the subject, and which must be of little or no use to the general reader. One cannot help wondering, for example, what sort of hazy notion the general reader will obtain from Figs. 61A-63, which show a colony of typhoid bacilli, and the typhoid bacilli themselves with and without flagella, the former called "spider" forms. The author is careful to inform the reader, on p. 266, that "the *size* of organisms is recorded in micro-millimetres = $\frac{1}{1000}$th of a millimetre commonly abbreviated μ", but avoids recording either the size of organisms which are figured in the book, or the magnification to which they have been subjected, except in one case where the magnification happens to have been included in the descriptive letter-press copied with the figure from another book.

It is equally objectionable to place together in one plate, objects requiring differing degrees of magnification, as in Fig. 13, which exhibits in a single view a gigantic cyclops, spores of moulds, a zoogloea mass of bacteria, &c. Such figures may be well suited for advertisements of filters in order to show up the horrors of drinking water *au naturel*, but must prove somewhat misleading to the reader who obtains his first ideas of such objects from this book. On p. 256 the reader is informed that the flagella of bacteria "should be looked for by careful staining with iodine, fuchsine or other reagent." It would be advisable for any one who wishes to see these curious appendages of bacteria to select the "other reagent" referred to, for the employment of those named would be quite inadequate for his purpose. On p. 257 the author falls into the common error of supposing that aerobic organisms "are incapable of existing in absence of air"; as a matter of fact, when deprived of free oxygen they can lie dormant for very long periods of time, and wait for its advent as a signal for the renewal of their activity.

It is a little curious that an author who desires to inform his readers on such up-to-date topics as the staining of the flagella of bacteria, "spider-forms" of typhoid bacilli, and the latest methods of examining a sample of water for typhoid and cholera, should lay such stress on the history and properties of "the divining-rod." In the midst of a very useful *résumé* of facts bearing on the movements of water in various strata, on subsoil-water, line of saturation, "faults" and artesian wells, the author offers the following rather startling advice to the "local authorities and others" who may be in search of underground water. Instead of advising them to consult an engineer or geologist, as one would expect from the geological treatment of this part of his subject, we read on p. 77—

"It is worth while for any one who has occasion to seek for underground water, before going to the expense of boring, to employ *first* (the italics are the author's) a 'water-finder,' and at the same time to invite a scientific authority to test the process in detail without bias, as the practical success seems sufficient, if not to shadow a new law, like the discovery of the Röntgen rays, yet by explanation to put this peculiar power in a position where it could be more largely useful and less hesitatingly accepted."

From the account given of a certain experiment with the divining-rod, the unknown power seems to act even

violently at times, for we read that "the tendency to twist itself on the twig's part was so great that on our holding firmly on to the ends it split and finally broke off."

We are even given the name and address of a "successful water-finder," "who states that he is only affected by running water and quite passive to stagnant." He says that "various kinds of wire or a watch-spring answer the same purpose as a twig or rod. A large number of people have the power to a certain extent." He adds, "I now use my hands alone, holding them out with palms towards the earth. I reckon the rod as an instrument only, and that the power itself is in the person."

On the same page, however, the last conclusion of the water-finder is contradicted by the experiences of a certain noble Lord with another "well-known 'dowser' or water-finder" (name and address given), for we read that "the effect produced on the twig emanated from a power outside himself." Moreover, the author states that "It" (the divining-rod) "is said to be still in vogue in Pennsylvania for petroleum, and in Cornwall for metallic lodes."

A very useful instrument apparently, and it seems a pity that its use is not better appreciated. The only form of "divining-rod" on which I should put the least trust, is one which may be seen nowadays carried about the streets of London by officials of the water companies, whose duty it is to detect "underground water" *running to waste*. Their instrument is certainly in the form of a rod, but it may be likened to a stethoscope, and its use depends upon its well-known acoustical properties rather than upon any mystic force still unclaimed by science.

The statements about the dissolved gases in water are exceedingly loose. On p. 251 we read that "a fully aerated water contains about 6 cc. of dissolved oxygen per litre." This is perfectly true for a temperature of 22° C., but for the cold water of winter 9 cc. is nearer the mark. A few words more would have explained the influence of temperature on the solubility of gases in water. On pp. 12-13, too, the following statement is misleading. "Water can dissolve at ordinary temperatures about its own volume of carbonic acid, 3 per cent. of oxygen and 1½ of nitrogen." Coming as it does after references to the fact that a fully aerated water contains, in the dissolved state, the natural constituents of the atmosphere, oxygen, nitrogen and carbonic acid, and that these gases are given off on boiling, one naturally concludes that these figures refer to the relative proportion of the three gases so dissolved from the atmosphere; but such is not the case, the figures refer to waters artificially saturated in the laboratory with the three gases in the pure state, and not mixed together as in atmospheric air, a fact which is not made clear. Naturally aerated, pure water contains, as a matter of fact, just about double as much nitrogen as oxygen. Again, on p. 191, the following inadequate statement is found: "Among the gases dissolved by water from the atmosphere, carbonic acid, being the most soluble, . . . occurs in the largest proportion." It is perfectly true that carbonic acid is the most soluble of the three gases of the atmosphere, but under the law of partial pressures, its greater solubility is more than counteracted by the small proportion of that gas present in the mixture, the result being that nitrogen (although having the lowest solubility of the three) occurs in the largest proportion, on account of its being present in the atmosphere in much greater proportion by volume than either oxygen or carbonic acid. Actual analyses of the gases given off on boiling in vacuo, from natural water having a surface freely exposed to air, often show less carbonic acid than nitrogen; but if the water has passed through strata containing carbonic acid, or is very impure, and bacteria are thriving in it and producing carbonic acid, this gas may exceed the nitrogen in volume; but in these cases the gas is not dissolved from the atmosphere, and in fact the excess diffuses into the atmosphere under conditions of perfect aeration.

Notwithstanding the defects which have been noted, the book is one which is well worth reading by "members of local authorities, sanitary officers, and others," for whom the book is avowedly written, who desire a general rather than a special knowledge of the present aspects of the subject, with all the recent advances which have been made in it. Nevertheless, as a little knowledge is a dangerous thing, local authorities will do well, when face to face with a water problem, to take the opinion of experts, and regard any knowledge gained by the perusal of this book as a negligible quantity where practical decisions have to be made regarding water supply or water purification.

For the serious student of the subject, who wishes actually to perform the chemical and bacteriological examination of water, or to make an independent interpretation of the results of analyses, the volume will be of little value.

Joseph Lunt.

THE LAND OF THE LAMAS.

Mongolia and the Mongols. Results of a Journey made to Mongolia in the Years 1892-1893. By A. Pozdnéeff. Vol. i. Published by the Russian Geographical Society. 4to, pp. 696, with many photo-engravings. (Russian.) (St. Petersburg, 1896.)

THE author of this work is a well-known specialist in Mongolian and Manchurian dialects. He visited Mongolia, for the first time, in 1876, and brought home a remarkable collection of 972 volumes of both printed and MS. works on the history of Mongolia, which prove that our former conceptions of Mongolian historical literature, as being entirely permeated with an ultra-Buddhist spirit, were utterly incorrect. For the last fifteen years, M. Pozdnéeff was professor of Mongolian dialects and literature at the St. Petersburg University, and he has published a great number of smaller monographs on different subjects connected with Mongolian literature and administrative organisation, as well as a big work on Mongolian monasteries. His name is not unknown either in this country, as he edited for the Bible Society various publications in Mongolian, Kalmyk, and Manchurian.

The present volume contains the diary of his first year's journey, from Kiakhta to Urga, Ulyasutai, Khobdo, back to Urga, and thence to Kalgan, during which journey he visited several interesting monasteries on or near to his route, copying valuable inscriptions, minutely describing Buddhist, or rather Lamaite monasteries and temples,

studying in the *yamuns* and in practice the administrative organisation of Mongolia under both the Chinese rule and the modifying influence of Mongolian common law, and paying attention at the same time to the interests of Russian trade in that immense territory, which begins to be dotted with Russian trade factories. In this work he was much helped by his wife, Mme. Olga Pozdnéeff, who travelled with him all the time, and by M. Fedoroff, who acted as a photographer of the expedition. Many of the photographs, chiefly of landscapes, ancient burial-places, old stone monuments, and monasteries, not to omit a portrait of the present grand-priest and "incarnation" of deity—the Urga *khutukhta*—are most interesting.

It is intended to publish the entire work in seven volumes, two of which will be given to the diaries of the expedition, one to the administrative organisation of the country, and one to Lamaism, which widely differs from the "Sakia-munism" that has lately been so much studied in Western Europe. The fifth volume will be devoted to various ethnographical materials, chiefly to folk-lore; the sixth, to trade; and the seventh, to a history of the prince families of Mongolia.

It would be utterly impossible to sum up in this place the volume which we now have before us. The routes followed by M. Pozdnéeff being well-known to geographers, only small additional geographical features could be gleaned here and there. On the contrary, the diary is full of small details about the features, the character, and the aspects of the towns of Urga, Ulyasutai, and Khobdo; the monasteries visited by the author; the organisation of the Chinese and Russian post in Mongolia; the relations between the local functionaries and the higher ones at Pekin, and so on. Some little scenes of the life of these functionaries, which are scattered through the diary, are worth pages of description, but they could hardly be mentioned without entering into many details. The same must be said of the monasteries, each of which has its own individual importance in the religious and political life of the country; Urga, for instance, which is the residence of the deity of Mongolia—the *khutukhta*—and the seat of a steadily increasing population of Lamas (they numbered 13,850 in 1889), is the political centre of the country—"its St. Petersburg," as the author says; while the monastery of Erdeni-tsu is its "Moscow"—that is, the heart of the country, and a living witness of all the chief events of the history of Khalkha Mongolia, where every temple and chapel, and every one of the ninety-two towers of its outer wall has a significance for the inhabitants.

A special chapter, which has a real historical value, and gives a deep insight into the present conditions of Lamaite Buddhism under Chinese rule, is the chapter devoted to the "incarnations," past and present, of *bodisatva*, in the persons of the subsequent *khutukhtas*, or grand priests and deities of Urga. These "incarnations," as is known, take place in Tibet; that is, plainly speaking, a boy is selected for that purpose by the Tibet Lamas, and brought and enthroned with great pomp at Urga. The history of these "incarnations" for the last three hundred years is very edifying.

The second volume will contain the diary of the expedition during the year 1893. P. K.

OUR BOOK SHELF.

Rough Notes and Memoranda relating to the Natural History of the Bermudas. By the late J. L. Hurdis. Edited by his daughter, H. J. Hurdis. 8vo, pp. viii + 408. (London: R. H. Porter, 1897.)

THAT a group of islands where the list of resident native land birds comprises only seven species, in addition to which four maritime kinds frequent the coasts in summer, should be visited by no less than one hundred and twenty-eight other species, chiefly migrants, is a wonderful fact in natural history, and one worthy of the best attention of those interested in solving the problem of bird migration. To record the dates of the arrival and departure of these various migratory species, appears to have been the task set himself by the late Mr. Hurdis; and the present volume (portions of which have already appeared in another work issued as far back as 1859) is the result of his labours.

The work is in journal form, and is written somewhat after the style of White's "Selborne"; and if it lacks the charm of that classic, this can hardly be considered a fault on the part of its author. At the end of the notes on the Bermuda birds, a list of the migratory species is given. And here it is to be regretted that the dates of arrival and departure are omitted; while we look in vain for any theories of migration, or hints as to whence the wanderers came and to what lands they departed. But, in justice to the author, it must be remembered that the notes were written at a time when the importance of such observations was not ranked as high as it is at the present day.

It is not, however, by any means, to birds alone that the notes are restricted; and nearly a hundred pages are devoted to the other *feræ naturæ*, as well as to plants, climate and meteorology, geology, and the early settlement of the islands. The editor has, on the whole, discharged her share of the task well, although it would have been better had the repetitions of the names of the regiments to which the author's numerous fellow observers belonged been omitted. A few illustrations of birds and scenery would also have considerably lightened the perusal of a very readable book. R. L.

Das Wesen der Electricität und des Magnetismus auf Grund eines einheitlichen Substanzbegriffes. By J. G. Vogt. Pp. 134. (Leipzig, 1897.)

IN this pamphlet the author proposes a theory of electricity which is based on a new conception of the constitution of ether and matter. This conception of matter supposes that all bodies and the ether are to a certain extent continuous and made of the same material, there being in all cases an initial and final condition both of molecules and ether.

The reason for this new proposal seems to be more sentimental than substantial. The author does not consider that the modern molecule is an interesting body, as it has no object of its own in existence. The following sentences on page 7 of the introduction fairly represents the author's feeling on the subject:—"Es giebt nichts absurderes als der moderne kinetische Substanzbegriff nach welchem die Materie aus Atomen oder diskreten Massenteilchen besteht, die in der monotonsten Weise durch alle Ewigkeiten hin- und herschwingen. Etwas stupideres und sinloseres ist kaum denkbar, und nur trockene, vom bücherstaube der Jahrhunderte verschüttete Physiker konnten eine solche trostlose Idee aushechen."

The leading idea which the author introduces is that space is filled with continuous matter, and that there is distributed through it centres of condensation. Surrounding each of these centres is a quantity of matter, which forms a sphere. The material inside these spheres is always tending to become more condensed whether the sphere belongs to the ether or to an atom, which is

merely a collection of these spheres in a very high state of condensation. To illustrate this tendency to condense, the author compares it with the tendency of the sun and stars to cool and contract, and eventually to form bodies like the moon. This theory of the constitution of matter, we are told, explains all the natural phenomena of light, heat, electricity and magnetism, without a single contradiction.

Having tried to upset the existing theories, and having told us that this new theory will explain practically everything, the author, to our surprise, fails completely to put forward convincing proofs in support of its application to electricity and magnetism. A good example of the class of explanation with which the pamphlet abounds is to be found on page 48, where the loss of electricity from conductors in damp weather is alluded to. A positively charged body is supposed to be surrounded by layers of negative ether spheres—that is, by spheres having a larger radius than the mean ether sphere. These negative ether spheres are in a high state of tension, and when a water molecule comes into the space which they occupy it relieves this tension, and so partly discharges the conductor. If we accept this explanation, there is absolutely nothing to prevent us supposing that small particles could discharge a conductor without touching it, or without being connected to it by any other material except the ether, as the author supposes that the layers of negative ether spheres, above alluded to, extend to finite distances from the conductor.

Experience, however, will not allow us to accept such an explanation at all, for it has been perfectly well established that the vapour rising from an electrified surface carries with it no charge. In connection with the magnetism of the earth we find, on page 90, an interesting piece of information. We are there told that it is only those heavenly bodies which rotate that have polarity, and that, *consequently, the moon is non-magnetic!*

It is consoling to learn that the author has suffered hitherto so much from hostile critics that he can no longer be stung by the suggestion that his philosophy is "blank Unsinn." J. S. T.

Farm and Garden Insects. By Prof. Wm. Somerville. Pp. viii + 127. (London: Macmillan and Co., Ltd., 1897.)

A useful little *text-book* for beginners, and an excellent *reference book* for practical farmers. The three parts into which the book is divided are judiciously arranged. The first gives in a clear and distinct manner the rudiments of entomology, and forms, therefore, a useful introduction to the second part, which describes some of the most common insect pests whose ravages cause so much loss to the farmer and gardener. This loss may be very much modified if the simple precautions and remedies contained in the book are adopted. The appendix in a few pages gives most useful information about mites, ticks, &c.; not true insects certainly, but which, by attacking our domestic animals, and even man himself, cause an immense amount of irritation, inflammation, and consequent loss. Farmers, gardeners, and all interested in rural economy will do well to carefully study its pages.

Geology of North-east Durham. By D. Woolacott, B.Sc. Pp. vi + 84. (Sunderland: Hills and Co., 1897.)

This is an orderly account of the geological characteristics and history of North-east Durham. It is written in language easily understood by readers unacquainted with the elements of geological science, and will, therefore, interest a popular public as well as the student of British geology. The diagrams are very coarse; but this is doubtless due to the fact that they were prepared for publication in a weekly newspaper, in which the articles now reprinted originally appeared.

LETTERS TO THE EDITOR.

[*The Editor does not hold himself responsible for opinions expressed by his correspondents. Neither can he undertake to return, or to correspond with the writers of, rejected manuscripts intended for this or any other part of* Nature. *No notice is taken of anonymous communications.*]

Rate of Racial Change that accompanies Different Degrees of Severity in Selection.

It is well known, in a general way, that better results are obtained by breeding from very select specimens than from the less select; but the statement deserves to be expressed with greater precision. I will do so here, on the lines laid down in "Natural Inheritance" (Macmillan, 1889), using the constants there determined for the stature of British men, including among them the coefficient by which female stature may be corrected to its equivalent male value, and thereby eliminating all trouble due to sexual differences.

On this basis, it will be shown, by way of illustrating a general problem, how much the stature of a breed of British men would be raised in each successive generation, under different specified degrees of severity in selection; also the utmost limits of stature to which they could be raised in the several cases, no change of type being supposed to occur in the interim.

Degrees of severity in selection admit of being defined by the method of *centiles* (or *percentiles*) fully described in the above book. No ambiguity need arise in interpreting such a statement, as that a man occupies the ninetieth centesimal grade in stature among a population whose mean stature is 68·5 inches, and whose individual statures are normally distributed about that mean with a quartile of 1·5 inches. Referring to Table 8 in the book, it is seen that the normal deviation at 90° in a series whose quartile is 1, is 1·90; therefore, in the above case, its value is $1{\cdot}9 \times 1{\cdot}7$ inches $= 3{\cdot}23$ inches. The mean stature of the population is 68·50 inches, which has to be added to this, making a total of 71·73 inches. Consequently when it is said that those persons are selected for parents who occupy the grade of 90° in their respective series, the degree of severity in the selection has been strictly defined. Similarly in respect to any other grade, such as 80° or 70°. This method of defining severity of selection is applicable to every measurable character, and to every form of distribution, skew or other, revealed by observation.

The principle has been fully explained in the above book, by which successive generations of the same population are able to maintain the same statistical peculiarities notwithstanding the "scatter" of families. It was shown that the sons of parents of similar statures form a co-fraternity, whose mean is more mediocre than the parental statures. In other words, the mean of the co-fraternity *regresses* towards the mean of the race, the coefficient of regression in stature being 2/3. Thus the children of parents of grade 90° in stature, deviate on the average no more than $2/3 \times 3{\cdot}23$ inches, or 2·15 inches, above the mean of the race. So much for the first generation of the selected parents.

In the second and subsequent generations, the "scatter" of the co-fraternities has to be considered. The quartile of every one of them was shown in the book to be 1·5 inches, consequently the individuals who occupy the grade 90° in a co-fraternity, are $1{\cdot}5 \times 1{\cdot}90$, or 2·85 inches taller than the mean of the co-fraternity, which itself is 2·15 inches above the mean of this race, making a total of 5·00 inches. The mean of their offspring, that is of the individuals forming the second generation of the selected series, is 2/3 of 5·00 inches, or 3·33 above the mean of the rest of the race.

These results are easily generalised and thrown into a formula, as follows: w = coefficient of regression; t = tabular deviation at the specified grade; q = quartile of race; q' = quartile of co-fraternity; $\alpha = t/q$; $\beta = t/q'$. Then the mean deviation of the pedigree stock from the mean of the race, in each successive generation, is:—

1st generation, $w\alpha$.

2nd ,, $w(w\alpha + \beta)$.

nth ,, $w^n\alpha + \frac{w - w^n}{1 - w}\beta$.

When n is large, w^n disappears and the limiting value becomes $\frac{w}{1-w}\beta$. If $w = \frac{2}{3}$ as above, the limiting value is equal to 2β.

On these bases the following table is calculated :—

Excess of the mean stature of the pedigree breed in each successive generation, above that of the rest of the population, when both parents occupy the undermentioned grades in their own generation of the pedigree-breed.

Generation.	99°	95	90	80	70
	inches.	inches.	inches.	inches.	inches.
1	3·9	2·8	2·2	1·4	0·9
2	6·1	4·3	3·4	2·2	1·4
3	7·5	5·3	4·1	2·7	1·7
4	8·4	6·0	4·7	3·1	1·9
5	9·1	6·4	5·0	3·3	2·1
&c.	&c.	&c.	&c.	&c.	&c.
Limiting values ...	10·4	7·3	5·7	3·8	2·3

The importance to the breeder, of using highly selected parents, is *measured* by these tables, and shown to be very great. Thus one generation of the 99° selection is seen to be more effective than two generations of the 90° selection, and to have about equal effects with those of an 80° selection carried on to perpetuity. Two generations of the 99° selection are more effective than four of the 95°, and than a perpetuity of the 90°.

It must be borne in mind, that there is no stability in a breed improved under the supposed conditions ; but that, as soon as selection ceases it will regress to the level of the rest of the population through stages in which the deviation at starting, sinks successively to w, w^2 . . . w^n of its value. It may, however, happen that a stable form will arise during the process of high breeding, that shall afford a secondary focus of regression, and become the dominant one, if the ancestral qualities that interfere with it be eliminated by sustained isolation and selection. Then a new variety would, as I conceive, arise ; but into this disputable topic there is no need to enter now.

We can thus understand the facility with which races of butterflies acquire mimetic forms, the severity of selection in their case being very great, while one of their generations occupies only a year. FRANCIS GALTON.

The Effect of Röntgen Rays on Liquid and Solid Insulators.

OWING to my absence from Cambridge in the Easter vacation, I have not until to-day seen the paper by Lord Kelvin, Dr. Beattie and Dr. M. Smolan (NATURE, March 25), on the influence of Röntgen rays on electric conduction through air, paraffin, and glass, in which the authors state that they cannot detect any influence of Röntgen radiation on conduction through solids. I think that the difference between this result and the one obtained by Mr. McClelland and myself arises from the temporary character of the effect of the radiation on solids. The increase in the conductivity of solids is only appreciable for a short time after the application of the electric force (see NATURE, July 30, 1896, p. 306) ; under long-continued electromotive forces the conductivity seems unaffected by the rays. The effect might perhaps be more accurately described as an increase in the electric absorption, rather than as an increase in conductivity. I have been for the past few months engaged in experiments on the effect of the rays on solids and liquids, particularly liquids ; and, though the experiments have been much interrupted by the pressure of other work, I hope soon to have them ready for publication. There is one experiment, however, which may be of interest. Of all the liquids tried, that sold as vaseline oil has proved the best insulator ; in its pure state it is very transparent to Röntgen rays, so to increase the absorption of these rays I stained the oil with iodine, when it became very opaque to them. The oil does not insulate so well after staining as it did before, but the effect of a slight amount of conductivity is not of importance when the following method is used. Three electrodes, A, B, C, are placed in a leaden vessel filled with the oil. B, which is between A and C, is connected to one pair of quadrants of an electrometer, A and C to the terminals of a battery of 1000 small storage cells. If there is any leakage the potential of B will, in general, not remain zero after the battery is put on, but it will do so if an earth connection is made at the proper place in the battery. The base of the vessel below B C was cut out, and an aluminium vessel inserted, so that the liquid between B and C could be exposed to the Röntgen rays. A balance was obtained with the rays off ; when the rays were turned on, the potential of B no longer remained zero, but changed in the way it would if the conductivity between B and C had increased. This effect was small but well marked, and seemed to last however long the electromotive force was kept on. J. J. THOMSON.

Cavendish Laboratory, April 24.

The Theory of Dissociation into Ions.

MR. SPENCER PICKERING has, in your number for January 7, brought forward certain difficulties which he says the advocates of the dissociation hypothesis have persistently ignored. I have been waiting in the hope that some one who supports the gaseous theory of solution as well as the theory of electrolytic dissociation would answer his letter. As no one has done so, I venture once more to trespass on your space.

First let me say that the experiment described by Mr. Pickering, in which water or propyl alcohol exudes through the walls of a semi-permeable vessel containing a mixture of these liquids, according as propyl alcohol or water is placed without, appears to me, as it does to him, to be very strong evidence that it is complex molecules of solution to which the walls are impervious. The experiment is one which certainly needs explanation at the hands of those who uphold the gaseous impact theory of osmotic pressure.

As I have already said, the idea that electrolytic conductivity depends on dissociation of the ions from each other, does *not* involve, as is so often assumed to be the case, the gaseous view of solution. The evidence for such dissociation appears to me to be exceedingly strong, as I will explain very briefly below, so that some explanation of the second experiment described by Mr. Pickering is necessary.

The experiment is this : The freezing point of a large quantity of acetic acid, to which is added a mixture of sulphuric acid and water in the proportions represented by $100H_2O + H_2SO_4$, shows that considerably less than 100 molecules have been dissolved. This result indicates that chemical union has occurred. Mr. Pickering says that, on the dissociation theory, the freezing point should be lowered by an amount corresponding to something between 101 and 103 molecules.

In such a case, however, we have conditions very different from those which hold when sulphuric acid is dissolved in water. In fact the liquid is in reality a mixed solution of water and sulphuric acid in acetic acid, or possibly, as Mr. Pickering suggests, of the hydrate of sulphuric acid in acetic acid. It does not at all follow that because sulphuric acid is dissociated in water, it is, therefore, dissociated in other solvents ; in fact, the freezing points of its solutions in acetic acid show that, on the contrary, aggregation has occurred. We should, therefore, expect that dissolving sulphuric acid in acetic acid would have little or no effect on the conductivity ; and this is also indicated by the low specific inductive capacity of acetic acid, which implies a low ionising power. There is no reason to suppose that the presence of a small quantity of water would modify the properties of the solvent enough to cause any appreciable change in the conditions.

But, even if these considerations were insufficient to explain the facts, the dissociation theory would not be discredited. As I pointed out in your issues of October 15 and December 17, 1896, dissociation of the ions from *each other* does not forbid the assumption that the ions are linked with one or more solvent molecules. Such a combination would explain Mr. Pickering's observation.

Mr. Pickering says that the dissociation theory depends solely on the numerical agreement obtained when properties of solutions are interpreted by its means. Although these numerical relations may have suggested the theory, they by no means furnish the only basis for it to rest upon. Other facts, to my mind, give much more conclusive evidence in its favour. As Mr. Pickering has challenged the supporters of the theory to explain his experiment, I may be allowed to ask the opponents of the theory to explain the following phenomena in any other way than by a dissociation of the ions from each other :—

(1) The velocity with which an ion travels through a dilute solution under an electric force is independent of the nature of the other ion present.

(2) The conductivity of a dilute solution is proportional to its concentration. The alternative to the idea of dissociation is to

imagine that the ions work their way through the solution by a continual series of interchanges between the parts of two solute molecules when in collision. The frequency of collision, and therefore the ionic velocity, would then vary as the square of the concentration, so that the conductivity would depend on the cube of the concentration.

(3) The potential difference at the contact of two solutions of different concentrations has the value calculated on the assumption that the ions migrate independently of each other, so that the faster-travelling ion enters the neighbouring solution first, and gives it a charge which continually increases till the electrostatic forces prevent further separation.

It is such phenomena as these, and not the numerical relations between conductivity and osmotic pressure effects, which seem to me to offer the most convincing evidence in favour of the dissociation theory. W. C. Dampier Whetham.

Trinity College, Cambridge, April 24.

Mosquito-Bites.

An acquired immunity from the bites of mosquitoes and "domestic pests" is not uncommon in British India, and I have rejoiced in it myself, but should not trespass on you for space for details. I can give them to any of your correspondents who may care to ask me.

There is lying before me a queer old case of mosquito-bite reported by a good witness, Pedro Teixeira, who sailed from Malacca to Mexico in 1600 A.D., and crossed the latter from Acapulco to San Juan de Uluâ, on his way to Spain. Of this journey he says: "Almost all along this road is a plague of mosquitoes, so terrible and grievous that no defence avails against them, *and they stung my best slave to death*."

102 Cheyne Walk, Chelsea, April 9. W. F. Sinclair.

THE NATURAL HISTORY OF WORMS.[1]

This is the third volume that has been issued of "The Cambridge Natural History." The previous volumes are vol. iii., Molluscs and Brachiopods (reviewed in Nature, liii. p. 149), and vol. v., Peripatus, Myriapods, and Insects (reviewed in Nature, liii. p. 322). In the multitude of the divisions in the animal kingdom with which it deals, the present volume differs considerably from its predecessors. It is true that one may even nowadays find most, if not all, of the many forms of life here described included in one heterogeneous section entitled Vermes; but the editors of the present book fully recognise the great distinction that exists between such forms as the Platyhelminthes or flatworms, the Oligochæta or earth-worms, the Rotifera, and the Polyzoa, and they have very wisely distributed the various sections to authorities whom every one will recognise as among the most competent to deal with their respective subjects. Indeed it may be questioned whether the separation of the subjects has not been carried a little bit too far. It is true that pages ix. to xii. contain what purports to be the scheme of classification adopted in the volume, but this is little more than a table of contents, in which no attempt is made to show the relationships of the orders or families mentioned; and, apart from this, the only bond of union between the various sections appears to be the quotation, very happily adapted from André de Chénier, "Nous allons faire des vers ensemble." We should much like to have seen some attempt on the parts of the editors to present their readers, all of whom are not supposed to be familiar with the newest ideas of zoology, with a short introduction showing how and why it is that this "old group of Vermes" has gradually been dismembered, so that now we find not only such forms as the Platyhelminthes and the Polyzoa claiming to rank as independent phyla of the animal kingdom, but we also find, in the scheme of classification at all events, the genus *Phoronis*, the few forms composing the Dicyemidæ and Orthonectida, and the thirty or so genera of leeches placed on the same high level. When we are told, as

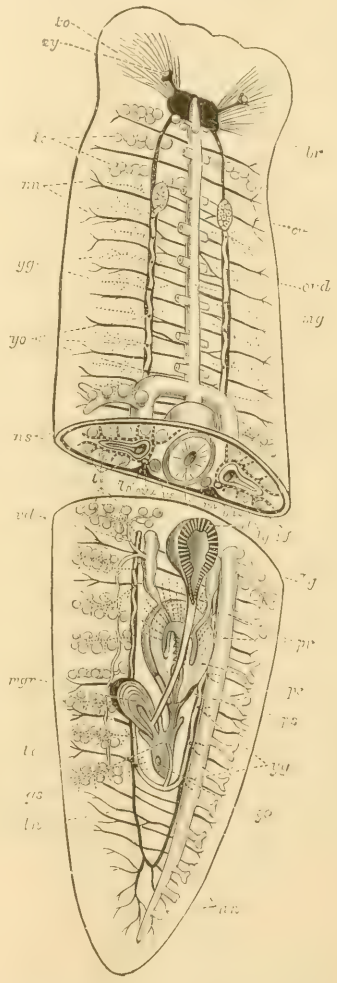

Fig. 1.—Diagrammatic view of the structure of *Planaria lactea*, a Turbellarian. × 7. The body has been cut across and a portion removed.

Mr. Gamble tells us, that the Turbellaria "occupy the lowest position in the whole group of worms," that they "are most closely allied to that great extinct group from which they, the Nemertinea, Rotifera, and even the Annelids, offer increasingly convincing evidence of having been derived," then we ask, What are we to

[1] "The Cambridge Natural History." Vol. II.: Flatworms and Mesozoa, by F. W. Gamble; Nemertines, by Miss L. Sheldon; Thread-worms and Sagitta, by A. E. Shipley; Rotifers, by Marcus Hartog; Polychaet Worms, by W. Blaxland Benham; Earthworms and Leeches, by F. E. Beddard; Gephyrea and Phoronis, by A. E. Shipley; Polyzoa, by S. F. Harmer. The whole edited by S. F. Harmer and A. E. Shipley. 8vo. Pp. xii. + 560; with numerous illustrations in the text. (London: Macmillan and Co., Ltd., 1896.)

understand by "the group of worms"? What are the characters of "that great extinct group"? while there may even be many who will ask, What does Mr. Gamble mean by the Annelids? All these questions will be asked in vain, so far as the "Cambridge Natural History" is concerned, if we except one small allusion to the "old term Annelida," which occurs in Mr. Benham's contribution; and it is answers to these questions, and to others like them, that we think should undoubtedly have been furnished by the editors. A similar complaint has been made in more than one place concerning the previous volumes of this series, and we venture to think that the complaint is especially justified in the present instance, if we are to regard this work in the light of anything else than a cyclopædia intended for the convenience of the fairly advanced zoologist.

When so many writers combine in a volume of this kind, it would be too much to expect that each of them should write on precisely the same lines or in a similar style; indeed, if we remember rightly, the prospectus of the "Cambridge Natural History" stated that considerable freedom would be allowed to individual authors. None the less, some attempt should have been made to settle how far this work is intended to be a popular one, since this is undoubtedly a question which the various authors have answered in exceedingly different ways. So far as we ourselves understand the aim of the series, nothing could be better or more appropriate than the chapters on Polyzoa, contributed to this volume by one of the editors, Mr. Harmer. Beginning with an allusion to common forms that may be found on the sea-shore, describing the beauty that a very slight examination will disclose in an unattractive-looking "dry piece of a brown paper-like substance," *Flustra foliacea*, he leads his reader on by gentle degrees to understand the meanings of the words "zooecia," "avicularia," and the like, and then explains to him the general characters of the Polyzoa. This done, the reader can appreciate with rather more interest the short account of the history of our knowledge of the group, and is prepared to learn in further detail the characters upon which the classification is based. The account of the various groups is interspersed and enlivened by remarks on their habits and life-history, containing many observations which appear to us to be original. The section ends with not the least valuable portion, a guide to the genera and to many species of British marine Polyzoa, with an account of how to make the necessary preparations. Whatever opinions we may hold with regard to the different points in Mr. Harmer's chapters, it does not seem to us that a better method for interesting and instructing, as well as for encouraging further research, could be devised.

It were to be wished that Mr. Harmer had opened the whole series with this section of his, or that he had had it printed and sent round to the various contributors for their guidance; for it cannot be said that his collaborators, at least in this volume, have been equally happy in their mode of attacking what we admit to be a very difficult problem. It does not, for instance, strike us that the average reader is likely to feel himself further drawn to the study of natural history in general or to that of the Chætopoda in particular, by the opening sentences of Mr. Benham's narrative, nor will the reader who has yet to learn what a gephyrean is, be particularly interested by such a paragraph as this:—

"The animals included in the above-named group were formerly associated with the Echinodermata. Delle Chiaje states that Bohadsch of Prague in 1757 was the first to give an accurate description of *Sipunculus* under the name of *Syrinx*, but Linnæus, who noted that in captivity the animal always kept its anus directed upwards, re-named it *Sipunculus*. Lamarck placed the Gephyrea near the Holothurians; and Cuvier also assigned them a position amongst the Echinoderms. He mentions *Bonellia*, *Thalassema*, *Echiurus*, *Sternaspis*, and three species of *Sipunculus*, one of which, *S. edulis*, "sert de nourriture aux Chinois qui habitent Java, et qui vont la chercher dans la sable au moyen de petits bambous préparés"—a paragraph that forms Mr. Shipley's introduction to the group.

Adequately to discuss and to criticise these numerous contributions would lead us into details more fitted for a technical zoological journal; but there are one or two thoughts that have occurred to us in reading the book, and these may perhaps be mentioned.

Is it not rather misleading to retain a name of such definite meaning as the name Mesozoa for the strange animals that compose the families Dicyemidæ and Orthonectidæ, and moreover to print this name Mesozoa in the scheme of classification with similar type and in similar position to the names of the recognised phyla, when, as Mr. Gamble himself tells us, they "are most conveniently (and probably rightly) considered as an appendix to the Platyhelminthes"? If the name be kept at all, it should at least be explained to the inquiring mind what those features are which made Van Beneden, the discoverer of the group, consider these animals as intermediate between the Protozoa and the Metazoa.

A somewhat similar point is the hesitation as to the position of the Nemertines; they are treated in a separate section by a separate author, Miss L. Sheldon, and yet it is pretty clear that she inclines to the view that they should be placed among the Platyhelminthes—that is to say, if Bürger's recent discovery of flame-cells be not disproved We do not mean to say that we wish Mr. Gamble and Miss Sheldon to exercise anything but a scientific caution. Nevertheless, these are excellent instances of the questions that might so well have been discussed in a separate chapter by the editors.

There is naught of popular interest to be said about the Nemertines, so that Miss Sheldon's chapter, perhaps inevitably, reads much like an excerpt from the ordinary text-book of zoology. Mr. Gamble's lot is cast in happier places; he has to deal with the tape-worms, the liver-flukes, the formidable *Bilharzia*—the cause of hæmaturia, and other creatures of as much economic as zoological interest. With reference to the liver-fluke of the sheep, Mr. Gamble speaks as though its intermediate host were only the water-snail, *Limnæa truncatula*, or varieties of that species. The Rev. W. Fielder and others, however, in Victoria, have recently discovered large numbers of the peculiar stages known as *redia* and *cercaria* in species of other fresh-water molluscs belonging to the genera *Isidora*, *Segmentina*, and *Planorbis*; and since these larval stages are similar in form to those found in *Limnæa truncatula*, there is reason to suppose that we have to do with the ordinary sheep liver-fluke. In any case, a large number of intermediate hosts, not mentioned in Mr. Gamble's table on pp. 71 and 72, have been noticed by the energetic Victorian naturalists.

A similar addition might have been made on p. 143, where *Strongylus*, a genus of nematodes or thread-worms, is mentioned as being found in horses, cattle, and sheep, birds, and reptiles, but not as having been found in man. Looss not long ago described a species, *Strongylus subtilis*, found in the intestines of Egyptian fellaheen, while more lately still Prof. Ijima, of Tōkyō, has stated that a species, which appears to be the same, has long been known in Japan as a human endoparasite. A plague that in March 1889 spread among the inhabitants of the Miura peninsula appears to have been due to the growth of this species. Mr. Shipley mentions that no intermediate host has been satisfactorily demonstrated; it may, therefore, be of interest to mention that Dr. Ogata, who investigated the Miura plague, and first discovered the existence of *Strongylus* in the stomach of one of its victims, believed, after much investigation,

that it had been brought about by the eating of certain oysters. The oyster has had so many attacks made on it of late, that it seems almost cruel to suggest that it might possibly serve as the host of this new endo-parasite.

The next two writers present us in the course of their articles with a new classification apiece. Prof. Marcus Hartog deals with the Rotifers, animals which are known to all amateur microscopists in such beautiful and interesting forms as *Melicerta ringens*, with its little tube of pellets. It is, however, not only to the microscopist, but to the advanced morphologist, that the rotifers are, as Mr. Hartog says, "a subject of keen interest." The resemblance of some of them to the larval form known as a trochosphere caused Huxley, in 1851, to draw the conclusion "*that the Rotifera are the permanent forms of Echinoderm larvæ*, and hold the same relation to the Echinoderms that the Hydriform polypi hold to the Medusæ, or that *Appendicularia* holds to the Ascidians." The relation to the trochosphere has also been insisted on by no less writers than Lankester, Balfour, Hatschek, and Kleinenberg, while quite recently Haeckel has endeavoured to show that such a Rotifer as *Notens quadricornis* presents a strong resemblance to what he, if not others, believes to have been the earliest type of Echinoderm. Mr. Hartog, however, has "been induced to take a view of the structure of Rotifers that brings it into close relationship with the lower Platyhelminthes, and with the more primitive larva of the Nemertines termed *Pilidium*."

"If we compare this organism with a Rotifer," he writes, "we find that the wreath corresponds in both, the funnel of the disc in such forms as Floscullariidæ and *Microcodon* leading to the mouth of *Pilidium*, while the gut is blind in Asplanchnidæ and in some of the highly developed Seisonidæ. The circular nerve-ring of *Pilidium* is in many Rotifers only represented by its anterior part, the brain, though in Bdelloids a sub-œsophageal ganglion completes the ring. This leaves a difficulty with regard to the apical sense organ; but it is easy to understand that an organ of sensation should become an organ of fixation. In this case the foot with its glands would correspond to the sense organ of the Trochophore larva; and it retains its primitive ciliated character in the larvæ and males of many Rotifera, and the adult female of *Pterodina* and *Calliidina tetraodon*. Embryology tells us that the anus of Rotifers cannot be homologous with that of Annelids, &c., for it is formed outside the area of the blastopore: it is an independent formation, probably due to the coalescence of the originally blind intestine at its extremity with the earlier genito-urinary cloaca. On this view we must change the orientation of the Rotifer, and place it, like a Cuttlefish, mouth downwards: for 'anterior and posterior' we must substitute *oral* (or *basal*) and *apical*; for 'dorsal' and 'ventral' we must use *anterior* and *posterior*; while 'right' and 'left' are unchanged."

We do not altogether agree with Mr. Hartog's views regarding the apical sense-organ. Nevertheless, it does not necessarily constitute a serious difficulty, since it is well known that sense-organs can be developed afresh in almost any part of the body where they may be required. The whole suggestion, moreover, is extremely interesting, and so far as the needs of such a Natural History are concerned, we can have no quarrel with Mr. Hartog, seeing that, "as these views are now published for the first time," he has "thought it wiser to keep to the accepted relations in the general description, a course which has the advantage of avoiding difficulties in the study of the literature of the Class."

Mr. Benham, in dealing with the Polychæta, has not been so wise, for he adopts a classification that has previously been put forward, and that in a slightly different form, only at the meeting of the British Association in 1894, and has not yet met with any acceptance. This classification, however, he not only reintroduces, but permits to govern the whole arrangement of his section. Apart from our strong presentiment that few workers on the Polychæta will accept this classification without considerable question, we cannot think that it is altogether fair to the readers to introduce so great a novelty in what after all professes to be a popular work. Mr. Benham, however, as we have already hinted, can hardly claim to have made his contribution particularly popular, except, indeed, where he quotes, as we are glad to say he does pretty often, that fascinating and suggestive writer, Sir J. Dalyell. Passing to Mr. Benham's chapter xii., we find that it purports to contain a "description of British Genera and Species." It is true that a certain number of species found in the British area are described in more or less cursory fashion, but whereas some of the species so described are definitely stated to occur around our coasts, others are merely put down with such a locality as "Atlantic," and it is not always stated whether or no they can be regarded as British. In other respects, too, this heading is not quite accurate, for many of the species mentioned are not described, while others which do occur are not even mentioned. We may note in passing that the curious parasite of crinoids known as *Myzostoma*, recently found, by the way, to occur also in two genera of starfish, is regarded by Mr. Benham as a degenerate Chætopod.

The Oligochæta, which include the familiar earthworm, have been entrusted, most naturally, to Mr. F. E. Beddard. We notice that he includes in the group the little parasite of the crayfish, *Branchiobdella*, which, curiously, was omitted from his monograph. The family Discodrilidæ, in which it occurs, is placed among the Microdrili. Here also comes the family Phreoryctidæ, which Mr. Beddard considers to be low in the series, arguing from the generative organs of *P. smithii*. It should be noticed that Vejdovsky does not accept this position for the family, and would, in fact, refer this particular species to some other genus. In other respects, however, there can be little doubt that Mr. Beddard's account leaves small opportunities for criticism. There is just one small point in his account of the Hirudinea where, trying perhaps to be popular, he has fallen into a not uncommon error. "The former extensive use of the leech has led," he says, "to the transfer of its name to the doctor who employs it, the authors of the sixteenth century constantly terming a physician a leech." There seems little doubt but that it was the leech which derived its name from the physician. As Mr. Beddard's linguistic attainments might have shown him, the word *leech* is obviously derived from the Anglo-Saxon *lece*, a physician, a word which we still find in Scandinavian languages, as in the Danish *læge*. The use of *leech* as applied to *Hirudo medicinalis*, on the other hand, is strictly confined to the English language.

Following on the leeches comes Mr. Shipley with a remarkably up-to-date account of the Gephyrea, a group of some zoological importance as having so often and so long been placed with the Echinoderms, in consequence of their strong external resemblance to some Holothurians. Mr. Shipley, following most recent authorities, would derive them from the Chætopoda, their nearest ally in that group being *Sternaspis*, and would place the Echiuroidea nearest to that phylum, while the Sipunculoidea are regarded as allied to them, but as having departed further from the annelid stock.

It is perhaps a pity that the remarkable genus *Phoronis* should have been described in the present volume. It is true that earlier writers supposed it an off-shoot of the Gephyrea, and that Caldwell and Lankester have associated it with those animals along with the Brachiopoda and Polyzoa, more especially with the last. Mr. Shipley feels tempted to accept the recent

researches of Masterman, which, if confirmed, must result in the placing of *Phoronis* among those peculiar allies of the early ancestors of the vertebrates known as Hemichordata. Perhaps it will be possible to introduce

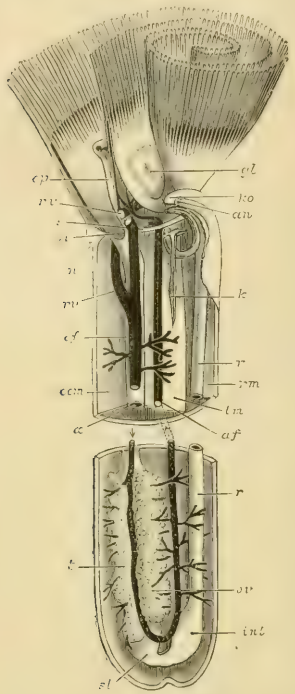

Fig. 2.—A schematic view of the interior of the body of *Phoronis*, with the middle ⅔ omitted. Magnification, which is great, is not stated.

it again in a subsequent volume for the convenience of comparative study. With regard to *Phoronis kowalevskii*, Mr. Shipley tells us that it is a name "given by

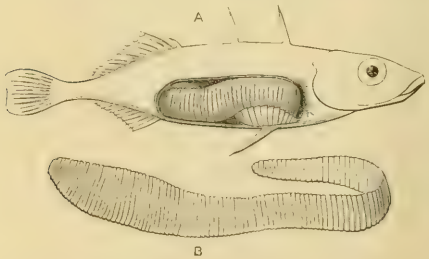

Fig. 3.—A. Stickleback (*Gasterosteus*) infested by an advanced larva of *Schistocephalus*. B. The larva. Both × 1½.

Benham to the species from Naples described by Caldwell, and replaces the name *Ph. cæspitosa*, which was given, but subsequently withdrawn, by Cori." This seems a roundabout way of stating that Cori's name was, as he has admitted, antedated by the name given by Benham. A name, once published, cannot be "withdrawn," even by its author

The volume concludes with an excellent index; but a review of any volume of the "Cambridge Natural History" that should conclude without an allusion to the admirable illustrations would indeed be incomplete. In this respect the present volume, though dealing with less picturesque animals, by no means falls short of its predecessors. As clear presentations of anatomical structure, we may draw attention to a diagram of *Planaria*[1] on p. 39, of *Leptoplana* on p. 14, of *Phoronis*[1] on p. 457, of *Alcyonidium* on p. 469, and many like them.

We may also notice the figures drawn from specimens in the Cambridge Museum, such as the stickleback[1] infested with a cestode larva, on p. 84, and many taken from the most modern writers, other than the authors, as Bürger, Haswell, Spencer, and others. Indeed, the only complaint we have to make with regard to the figures is that the name of the artist does not appear to be given in the volume.

Taken as a whole, the book is fully worthy of its place in this attractive series, and, even if the eye of a critical zoologist may detect a shortcoming here and there, his heart must be gladdened to see a general work published at last that treats these generally despised animals in a style to which their morphological importance entitles them.

INDIA-RUBBER AND GUTTA-PERCHA, AND THEIR SOURCES.

THE question of the supply of india-rubber to meet the present enormous demands caused by the progress of electrical science, and the rapid development of the application of the substance for cycle and carriage tyres, is one that has been much discussed of late, and continues to increase in interest. For some time past it has been well known that the trees which supply the best rubber known in commerce, namely, Para rubber, have been more and more difficult to get at, in consequence of the collectors having to proceed further into the forests in search of the trees (*Hevea brasiliensis*) which yield the valuable juice. But though greater distances have to be traversed in order to collect the rubber, there seems but little fear of the absolute failure of the rubber supply generally, or of this one particular kind. Though the quality of this rubber is of a very superior nature, we are fortunately not dependent alone upon it for the supplies of our markets, for from the East and West Coasts, as well as from Central Africa, and also from India and the Far East, we obtain very respectable quantities; indeed, the resources from tropical Africa in this respect have of late so much increased, that they promise to compensate for any loss of the American supplies, and the experiences of the past year or so, when a new source of rubber has been discovered at Lagos, is even more reassuring as to the future supplies, for other plants may yet be found capable of assisting in furnishing a substance that will probably, in the future, be in still greater demand than it is even now. So that it has become necessary for every one interested in this peculiar industry to take every precaution to prevent waste of material, both in the processes of collecting the milky juices and in the preservation of the plants yielding them.

It seems pretty certain that, whatever takes place in the discovery of new sources, the plants yielding these elastic juices must belong to one of three natural orders, for all the known plants furnishing rubber of commerce belong to the Euphorbiaceæ, the Urticaceæ,

[1] Reproduced here by permission of the publishers.

and the Apocynaceæ, as will be seen from the following summary.

Euphorbiaceæ (*Hevea brasiliensis*).—This is the source of the Para rubber already referred to, and the plant from which the earliest supplies of rubber were obtained when, in 1770, it first appeared in London as a new discovery for rubbing out pencil marks on paper, and realising about three shillings per cubic inch. At the beginning of the present century it began to be used in the treatment of woven fabrics, for air-tight and waterproof articles. So rapidly, indeed, did its use develop, that in the year of the Queen's accession Para rubber was imported into England to the amount of 141,735 pounds, and twenty years later it had increased to 3,477,445 pounds; while at the present time, when the trade returns are counted by hundredweights instead of pounds, the import accounts for 1896 showed the total of rubber from all sources to be 431,164 cwts., which were valued at 4,993,186*l*. The species of *Hevea* of which *H. brasiliensis* is the best known as a rubber producer are large trees, growing abundantly in the humid forests of tropical America, especially along the Amazon and its tributaries. As in most of the Euphorbiaceæ, the wood is soft and easily cut in the tapping process. The trees are locally known as Seringas. *H. brasiliensis* grows to a height of 60 feet, branching from the base. The collection of the milk commences about August, and is continued till the following January or February. In the wet season the milk is too watery to produce good caoutchouc. The trunk of the tree is wounded with a knife or a small axe-like instrument, a deep horizontal cut being first made a few inches from the base, and a vertical one from this, some distance up the trunk; oblique cuts are then made into this main channel, which conveys the milk into small clay vessels placed at the bottom to receive it. As these are filled they are emptied into a calabash or gourd, and when this is full it is carried to a more convenient place for coagulation; for this purpose, the contents of the calabash are emptied into a large earthenware basin. A kind of wooden paddle, with a widish blade and a long handle, is then dipped into the milk, and turned about over the smoke and heat of a fire made of the hard bony fruits of *Maximiliana regia*, or *Attalea excelsa*, which fire is enclosed with a thick earthenware covering, open at the top, like a small chimney, to allow the heat and smoke to escape. As the rubber coagulates upon the blade, in the form of a thin film, more milk is poured over it, and the same operation of holding it over the fire repeated. This goes on till a sufficient thickness of rubber is deposited, when it is cut through round the edge, and the paddle withdrawn. Various kinds of Para rubber are thus prepared, and are known in commerce under different names, according to the thickness of the deposit. The large round balls, generally known as "Negro-head," are made up of scraps of rubber tightly rolled together. This kind is often much adulterated, and one specimen in the Kew Museum contains in the centre, as shown when cutting the ball through, about one-third its weight of pieces of brickbat and cotton cloth.

Besides the process here described, some Para rubber is coagulated by the aid of alum, and by other means: but the quality of the rubber from this source is always good.

So far back as 1873, the necessity of securing supplies of rubber for future generations occupied the attention of the Kew authorities, and living plants of *Hevea brasiliensis* were sent to India, with the view of establishing the plant in that country. Smaller consignments were also made to the West Coast of Africa, Jamaica, Dominica, Trinidad, Queensland, Singapore and Java. The history of this important undertaking is fully recorded in the Reports of the Royal Gardens, Kew, for 1873, and subsequent years, where, indeed, will also be found recorded the various experiments made by Kew in the introduction of other rubber-yielding plants into countries that were thought suitable for their extension.

Another rubber-yielding plant of the Euphorbiaceæ is that which furnishes the kind known as Ceara Scrap, from the fact that this kind always appears in commerce in masses composed of agglomerated scraps. The plant is a native of Central America, and is known to botanists as *Manihot Glaziovii*. In 1876 a large quantity of seeds and plants of this species were collected in Central America, and brought to Kew; they were rapidly propagated, and plants were sent to Ceylon, Singapore, Calcutta, and other places, in most of which the plants grew rapidly and yielded rubber, thus proving their capability of establishing themselves in their new homes.

Urticaceæ.—In this order we find also a Central American rubber plant in *Castilloa elastica*, which, with perhaps some allied species, furnishes the commercial kinds known as Guatemala, Mexico, and West India rubbers. *C. elastica* is one of the species that has received much attention at Kew, and in 1876 was widely distributed. The Indian source of rubber (*Ficus elastica*) also belongs to this group of plants. The plant is so well known as a parlour plant in this country, producing its fine glossy leaves under almost any conditions, that the fact is scarcely realised that in India and Ceylon it produces a veritable forest of trunks, and covers the ground with its long-stretching buttresses or roots, which run sometimes for distances of 30 or 40 feet. It is the source of Assam rubber, which is collected by wounding the stems and buttresses in all directions. The milk is collected either in holes made in the ground, or into leaves folded in the form of a vessel to receive it. On the upper parts of the stems, or on the branches, the juice is allowed to coagulate by exposure. The largest yield is obtained in August, when, on an average, a tree will give about 50 ozs. of milk, yielding about 15½ ozs. of pure rubber. To prepare it for market it is sometimes poured into boiling water, and stirred until it is sufficiently firm to be carried about without sticking together. It is shipped from Calcutta in baskets made of split rattan, and mostly covered with a gunny bag. When cut the rubber has a mottled appearance, and is composed of pieces varying from cream, or flesh colour, to a bright pink, or even red. It is either in the form of separate stringy-like balls, irregular blocks, or large masses.

Another species of *Ficus*, namely, *Ficus Vogelii*, furnishes one of the kinds known as Lagos rubber. The tree is known in West Africa as the "Abba," or "Abo," and is fully treated of in the *Kew Bulletin* for 1888, p. 253, and 1890, p. 89. The quality of this rubber was never considered very satisfactory, as it was more or less resinous, and was consequently used for mixing with other kinds rather than by itself. Another kind of Lagos rubber has, however, since been discovered, which has proved to be of superior quality, and is next described.

Apocynaceæ.—To this order belongs the several species of *Landolphia*, climbing, branching, shrubby plants, supporting themselves on the surrounding trees of the forest. The stems of these plants average from 4 to 6 inches in diameter, and the principal species, furnishing what is commercially known as African rubber, are *Landolphia owariensis*, *L. florida*, and *L. Kirkii*. The quality of these rubbers, though mostly good, is by no means equal to the Para kind, but the discovery of a new source of Lagos rubber, from a tree known to the natives as the "Ire" or "Ireh," has given a great impetus to the trade of the West Coast of Africa in a rubber of extremely good quality. The *Kickxia africana*, unlike the species of *Landolphia*, forms a tree 50 to 60 feet high, with a trunk averaging 12 to 14 inches in diameter. It is said to be one of the most beautiful

trees of the forest, and is capable of producing in a good season as much as from 10 to 15 lbs. of rubber per tree. For the purpose of extracting the rubber, a deep vertical cut is made through the bark, and several oblique cuts on each side running into the main channel, at the base of which a vessel is placed to receive the exuding milk, which is coagulated by allowing a quantity to stand for some days in a cavity made in the trunk of a tree, so that the watery portion evaporates or soaks into the wood, leaving the solid portion behind, which is kneaded and pressed together into a solid mass, or the milk is placed in a vessel and boiled, the rubber beginning to coagulate almost immediately heat is applied. The whole history of this interesting discovery and development is given in the *Kew Bulletin* for 1895, p. 241, and 1896, p. 76, from which we learn that in January 1895, which practically marks the beginning of the industry, the exports were 21,131 lbs., valued at 1214*l*., and at the end of December of the same year this had increased to such an extent as to show a total for the twelve months of 5,069,504 lbs., of the value of 269,892*l*. 13*s*. 10*d*.

As the *Bulletin* remarks, "The history of this new rubber industry in Lagos is full of interest, and illustrates the wonderfully rich resources of the vast forests of West Africa. It shows also very clearly how largely these resources can be developed by judicious and intelligent action on the part of the Government."

Besides the important sources of rubbers already mentioned, there are still others belonging to the same natural order Apocynaceæ, natives of the Far East, which may be briefly referred to species of *Willughbeia* and *Leuconotis*. *Alstonia plumosa* yields a rubber in Fiji, whilst *Forsteronia floribunda* and *F. gracilis* yield rubbers in small quantities in Jamaica and Demerara respectively, though not in sufficient quantities to be of any commercial importance.

From the foregoing list of plants, it will be seen how generally distributed the elastic juices are in Apocynaceous plants.

Space will scarcely allow us even to mention the allied substance gutta-percha, the history of the introduction, development, and threatened failure of supply of which is fraught with so much interest and warning: how that in 1842 the substance was first discovered in Singapore, and the trees cut down in such large numbers to supply the European demand, that in five years after only a few trees existed in Singapore, and a similar fate attending the trees which were afterwards found in Penang, are facts that are well known as applying to *Dichopsis gutta*, a sapotaceous tree, upon which the reputation of gutta-percha was at first founded, and from which the bulk of the commercial supplies have continued to be drawn, though it is more than probable that a similar substance is yielded in the East by allied trees, the botany of which, however, is but imperfectly known.

A substance very like gutta-percha is furnished by *Mimusops globosa*, a large forest tree, growing to a height of from 60 to 70 or even 100 feet, in Trinidad, Jamaica, Venezuela, and British Guiana. It belongs to the Sapotaceæ, and the solidified milk, or gutta, was first brought to this country in 1859. Its use with us has fluctuated very much, and it cannot be looked upon as a perfect substitute for true gutta-percha.

The interest at the present time is much greater towards the rubber supplies than those of gutta, and this is borne out by a few facts referring to the probable demand, in the very near future, that have appeared in a recent number of our contemporary, *Commerce*, among them being a statement that the estimated output of cycles in Great Britain and the United States during the present year will amount to 1,750,000; besides this, there is the probable development of motor carriages, and the extended application of rubber for the tyres of ordinary vehicles. So that there is every probability that the interest in rubber-yielding plants will go on increasing.

John R. Jackson.

Museum, Royal Gardens, Kew.

THE RESOURCES AND THE NEEDS OF CAMBRIDGE UNIVERSITY.

His Grace the Duke of Devonshire, K.G., Chancellor of the University of Cambridge, has requested us to give publicity to a statement as to its financial position and requirements, which has been drawn up for him by an influential Committee of residents, and whose authority he states to be unquestionable. Its purpose is to make known to the public the true state of the University's finances in relation to its increased duties, in the hope that means may be found for raising its endowments to the level of its present requirements.

The statement seeks to remove the impression that the University is a wealthy body. The fall in agricultural values has so seriously crippled it and its constituent Colleges, that this impression is no longer justified; and a point has been reached at which, without new endowments, complete efficiency and necessary expansion are gravely impeded. Benefactions for the establishment of special prizes and scholarships have not been wanting; but the flow of contributions for general academic purposes has for years practically ceased, though it is such gifts that are most needed, and at present most likely to be widely useful.

It appears that while the Colleges undertake much of the teaching for the degree examinations in mathematics and classics, all the higher branches, and the entire round of the natural and physical sciences, are provided for by the University, which maintains the library, the observatory, the botanic garden, eight museums, and eight laboratories. The University staff consists of about 120 professors, readers, and lecturers, whose stipends are paid partly by the common fund, partly by their emoluments as Fellows and Lecturers of Colleges. A Professor's stipend of 700*l*. or 800*l*. is diminished by 200*l*. if he holds a Fellowship; but in nearly all the Colleges the dividend is less than this sum, and the Professor, therefore, does not receive his full nominal stipend. By the statutes there should be twenty Readerships at 400*l*. each: the University has been able to establish six only, and these, in general, at stipends of about 100*l*. to 150*l*. The University Lecturers are usually selected from the College staffs, and receive, as a rule, stipends of 50*l*. a year.

In consequence of the conditions established in 1881, four-fifths of the Fellowships are now held by resident graduates. The maximum dividend is fixed at 250*l*., but in fifteen out of seventeen Colleges this sum is not reached, and in some the dividend does not exceed one-third of the maximum.

The revenue for 1896 consisted of about 40,000*l*. derived from fees; about 16,500*l*. contributed by the Colleges as a tax on their revenues and tuition-fees; and about 6000*l*. obtained from the University endowments (tithes, rents, &c.). Of this sum, over 33,000*l*. was paid in stipends; over 22,000*l*. for the maintenance of libraries, museums, laboratories, &c.; some 2200*l*. in repayment of a loan for buildings; and 5000*l*. in part payment of necessary sites for new buildings adjoining the present museums.

From fees it is not easy to see how more can be derived without diminishing the number of students and graduates; the endowments are insignificant, and steadily decreasing in value; and the College contribution has already, in view of the financial difficulties of these corporations, been more than once reduced. When the tax reaches its maximum in 1902, the most it can yield, in addition to its present amount, is probably about 2000*l*.

On the other hand, greater expenditure is called for in

various necessary directions. The museums and laboratories have been practically created within the present generation, but already many of them require considerable extension and better equipment. Important branches of study are rightly claiming recognition, but their demands cannot be met without heavy capital outlay. New sites have been secured, but the money to build on them is not forthcoming. The University library must be extended; the school of law is without a building; the lecture-rooms for the literary and philosophical subjects are wholly inadequate; there are neither central offices for University business, nor suitable rooms for University examinations; lastly, the laboratories for botany, zoology, and pathology must be rebuilt; the departments of physiology, physics, and engineering need speedy enlargement, and the school of medicine (including pharmacology) is practically beyond repair, and must be reconstructed on another site.

It is pointed out that while the total divisible income of the Colleges has fallen by 34 per cent. in the last fifteen years, the number of students has increased to 3000. Much personal devotion and sacrifice on the part of the teachers, much self-denial on the part of the Colleges which have not reduced their scholarships, and other encouragements for the poorer students, and much enthusiasm for the progress of science and learning on the part of all, must have gone to produce a result so creditable to the University. It appears to us that a fair case has been made out for its substantial re-endowment in respect of many of its departments; and, though no appeal for subscriptions is made, the facts related in the Chancellor's statement may well be pondered by those who are in a position to display a wise liberality in the cause of education, learning, and research.

NOTES

At a meeting held on April 13, the Academy of Natural Sciences of Philadelphia conferred the Hayden Memorial Award for 1897, consisting of a bronze medal and the interest of the special endowment fund, on Prof. A. Karpinski, the Chief of the Geological Survey of Russia, in recognition of the value of his contributions to geological and palæontological science.

The Budget Commission of the French Government has decided that the sum of four thousand pounds be voted for the Pasteur Institute at Rhia-Trang, to encourage Dr. Yersin's researches on the plague serum. The Chamber of Deputies is asked to adopt this decision.

The *British Medical Journal* says there is a Bill before the New York State Legislature which provides for the establishment of a laboratory for the preparation of evidence for use in future trials for murder conducted by the State. In a recent case 1450*l.* was paid to medical witnesses for giving expert evidence. The object of the new Bill is to save this expense.

Sir Edward Newton, K.C.M.G., died at Lowestoft on April 25, in the sixty-fifth year of his age. The youngest son of the late Wm. Newton, of Elveden, in Suffolk, he proceeded to Magdalene College, Cambridge, where he took the usual degrees. Appointed, in 1859, Assistant Colonial Secretary of Mauritius, he successively became Auditor General and Colonial Secretary of that island, relinquishing the last post in 1877, on being appointed Colonial Secretary and Lieutenant Governor of Jamaica, whence he retired in 1883, through ill-health. He was a member of the mission sent by the Government of Mauritius to congratulate the late King of Madagascar on his accession to the throne; and, being an ardent ornithologist, availed himself of the occasion by materially increasing (as he did during a subsequent visit made with that express purpose) the knowledge of the very peculiar fauna of that country, which he was almost the first English naturalist to investigate on the spot. In like manner he largely increased our knowledge of the zoology of the Mascarene Islands generally, and it is mainly due to his exertions that nearly complete skeletons of the marvellous "Solitaire" of Rodriguez were recovered from the caves of that island, as described in the *Philosophical Transactions* of the Royal Society. Sir Edward was one of the founders of the British Ornithologists' Union, a Fellow of the Linnean Society, and a Corresponding Member of the Zoological Society of London.

We regret to see the announcements of the death of Dr. E. S. Bastin, professor of botany and materia medica at the Philadelphia College of Pharmacy, and of Mr. Louis P. Casella, the well-known scientific instrument maker.

The southern portion of Bronx Park, which the Commissioners of the Sinking Fund of the City of New York have just allotted for the use of the New York Zoological Society, embraces an area of about 260 acres. The city authorities will annually provide the funds for the maintenance and care of the buildings, animals and collections in the Zoological Garden which will be established in the Park; but the grant for the first year is not to exceed sixty thousand dollars. The erection and original equipment of the buildings, and the animals to stock them, have to be paid for by the Zoological Society, which has to raise one hundred thousand dollars by subscription before this time next year, and the further sum of one hundred and fifty thousand dollars within three years of the commencement of the work of converting Bronx Park into a Zoological Garden. Strong efforts are therefore being made to secure to the Society the sympathy and support of a large number of members. An attractive report on the plans and purposes of the Society has been printed and circulated, and in it Mr. William T. Hornaday, the Director of the proposed Garden, describes the zoological gardens of Europe, and dwells upon the advantages offered by Bronx Park. He holds that none of the Gardens he visited "occupies ground which can for one moment be compared, either in physical character or in extent, with the matchless site that has been chosen by this Society for the Zoological Park of America." One of the conditions of the grant of South Bronx Park to the Society is that the Zoological Garden and its collections shall be open free to the public for not less than seven hours a day, or at least five days a week.

The Belgian Royal Academy announces prizes, mostly of the value of 600 francs, to be awarded in 1898 for essays on certain questions connected with the following subjects: In mathematical and physical science—on the critical phenomena, on theories of the constitution of solutions, on the correspondences (*Verwandtschaften*) between two spaces, and on the influence of the radical NO_2 in certain compounds. In biological science—on the macro- and micro-chemistry of digestion in carnivorous plants, on the physiology of some invertebrate animal, and on the organisation and development of the *Platoda*. A further prize of 1000 francs is offered, in memory of Jean-Servais Stas, for the best determination of the atomic weight of some element for which this constant is at present uncertain.

In the last number of its *Proceedings*, the London Mathematical Society publishes the outlines of seven lectures on the Partitions of Numbers, which were delivered by the late Prof. Sylvester at King's College, London, during the year 1859. The outline of each lecture was printed shortly before it delivery, and copies handed to those in attendance. The Professor's attention was shortly afterwards diverted to another branch of mathematics, with the result that his researches on compound partitions have hitherto remained unpublished; but shortly before his death, Prof. Sylvester yielded

to the suggestion of the Council of the London Mathematical Society, so far as to assent to the publication of these outlines with all their imperfections on their heads.

ONE of the most important problems now attracting the attention of seismologists is the choice of a system of stations in which to carry out the seismic survey of the world. In the plans so far proposed, advantage would, for obvious reasons, be taken of the existence of astronomical observatories, care being at the same time exercised to obtain a nearly uniform distribution of stations over the earth's surface. Prof. G. Grablovitz has recently, however, made the important suggestion that these stations should rather follow the distribution of volcanoes and the great lines of fracture of the globe. He points out that the majority of active volcanoes are situated close to three great circles, and he proposes that seismic stations should be founded near the six points of intersection of these circles, and near twelve other points symmetrically placed on the three circles. There are several obvious difficulties in the way of such an arrangement; but it is, nevertheless, one that deserves a very careful consideration.

IN the *Bulletin de l'Académie Royale de Belgique*, M. P. de Heen attacks the ordinary accepted theory of the critical point, according to which the horizontal portions of the isothermals of a substance gradually diminish to a vanishing point, and the extremities of these portions lie on a continuous curve whose tangent is horizontal at that point. M. de Heen maintains that the rectilinear portion of the isothermals does not vanish at the critical point, but that just after passing that point its direction gradually becomes inclined to the horizontal axis.

IN the *Monthly Weather Review* for January, of the U.S. Weather Bureau, Mr. A. L. Rotch gives an account of the cloud observations being made at the Blue Hill Observatory, Massachusetts, since May 1, 1896, in accordance with the request of the International Meteorological Committee. There are three theodolite stations in the same straight line, at which simultaneous observations of height and velocity are made twice daily, when conditions permit. Points on the clouds are selected by telephonic communication, and, when practicable, from three to five observations are taken on the same point, at intervals of a minute, and are reduced by simple trigonometrical formulæ. The theodolite measurements are supplemented by other methods, devised by Mr. Clayton, to determine the heights of the lower clouds, including the use of kites. It is found necessary to employ these additional methods, because the low clouds are so indefinite in form, or cover the sky with such a uniform veil, that it is impossible to measure them with theodolites or photogrammeters. We may confidently look for valuable results from these persistent and careful observations.

THE *Meteorologische Zeitschrift* for March contains an interesting communication on the oldest meteorographs, for which we are indebted to the indefatigable bibliographical researches of Dr. Hellmann. It was known from Birch's "History of the Royal Society," that Sir Christopher Wren had constructed a meteorograph about the year 1660; but a complete description of the apparatus was wanting, as only a portion of it was shown in the plate. But Dr. Hellmann has discovered both a description and a sketch of the instrument in the *Journal des voyages de M. de Monconys* (Lyon, 1665-1666). As this work is scarce, although a later edition of it is in the Library of the Royal Society (London), Dr. Hellmann quotes the passages referring to the meteorograph, and reproduces the sketch. The rain-gauge, forming part of the instrument, was the first of its kind. During a visit to London in 1663, Monconys obtained particulars from Wren of a hygrometer which he had also invented, and a description and sketch of this are given in the *Zeitschrift*. Wren, therefore, constructed the second condensation hygrometer; but this does not appear to be generally known, as no mention is made of it in Mr. Symons's "History of Hygrometers" (*Quart. Journ. Meteor. Soc.*, vol. vii.). The first condensation hygrometer was invented by Prince Ferdinand II. of Tuscany, about ten years earlier.

THE effect of hardness on the electrical and magnetic constants of steel, with particular reference to the tempering of the magnetic parts of instruments, is the subject of a short paper, by Dr. Carl Barus, in the March number of *Terrestrial Magnetism*. The following rules, given by Dr. Barus, for the practical treatment of magnets, where great secular permanence of magnetisation is the principal desideratum, should prove of great service in physical laboratories and to scientific instrument makers. (1) Rods tempered glass-hard are not to be used as essential parts of magnetic instruments. (2) Having tempered a given steel rod in such a way as insures uniformity of glass-hardness throughout its length, expose it for a long time (say 20–30 hours; in case of massive magnets even longer intervals of exposure are preferable) to the annealing effect of steam (100°). The operation may be interrupted as often as desirable. The magnet will then exhibit the maximum of permanent hardness for 100°. (3) Magnetise the rod—whether originally a magnet or not is quite immaterial—to saturation, and then expose it again for about five hours (in case of massive magnets even larger intervals of exposure are preferable) to the annealing effect of steam (100°). The operation may be interrupted as often as desirable. The magnet will then exhibit both the maximum of permanent magnetisation as well as the maximum of permanent hardness corresponding to 100°. Its degree of magnetic permanence against effects of temperature (less than 100°), time, and percussion is probably the highest conveniently attainable.

WORKING in the physical laboratory of the Massachusetts Institute of Technology, Mr. R. W. Wood has succeeded in producing diffraction phenomena with Röntgen rays. The source of the rays was an arc-like discharge between two very small beads of platinum in a high vacuum. The discharge bulb was only about an inch in diameter, while the radiation (which came from an area about the size of a pin-head) was strong enough to show the bones in the fore-arm. The "arc" appeared to be a new form of kathode discharge, and could only be produced under peculiar conditions. Mr. Wood used a tube with a platinum slit 0·1 mm. wide, mounted within the bulb at a distance of 2 mm. from the radiating bead. The second slit of variable width was placed at a distance of 10 cm. from the first, and the photographic plate at distances varying from 10 to 30 cm. from this. The images of the slit on the plate showed a distinct dark line on each edge, which could only be explained on the supposition that interference occurred. The plate was at too great a distance from the slit for such an effect to be produced by reflection of the rays from the edges. Images of fine wires showed similar phenomena.

THE study of the origin and significance of ornamental devices and patterns is engaging fresh workers. In a recent number of *Globus* (Band lxxi. p. 197), H. Strebel discusses certain ornamental motives of ancient Mexico. The series of designs with which he is here concerned are attributes of the Wind-god, Quetzalcoatl. The similarity of these devices from the Pueblo Indians, right down to Peru, indicate that there was an original community of culture.

THE directors of the Biltmore Herbarium have prepared a catalogue of the duplicate specimens in the collection, with the view of effecting exchanges. The list represents mainly plants indigenous to Western North Carolina, which have been care-

fully dried and, in many instances, specially prepared for distribution. The catalogue can be obtained from the curator, Mr. C. D. Beadle, Biltmore, North Carolina, U.S.A.

In June 1895, Messrs. P. A. Rydberg and C. L. Shear were commissioned by the Secretary of Agriculture of the United States to pay a three months' visit to certain points in the States of Nebraska, Idaho, Montana, Utah, and Colorado, for the purpose of collecting roots and seeds of grasses and other forage plants, and of obtaining information from farmers and others as to their economic value. The Report of this Commission forms *Bulletin* No. 5 of the U.S. Department of Agriculture, Division of Agrostology. A large number of grasses are described and figured, and notes are appended with regard to their value to agriculturists.

The St. Petersburg Society of Naturalists, section of Botany, proposes to issue a full herbarium of the flora of European Russia, similar to Fries's "Herbarium normale" and to Kerner's "Flora exsiccata Austro-hungarica." It will be issued in parts of fifty species each, under the editorship of S. I. Korzinski, and every person who will send to the editor (St. Petersburg University) two species, represented by fifty specimens each, will be entitled to receive one part of the herbarium. A preliminary communication with the editor would save the trouble of a double collection of the same species, in which case the person who has sent its plants first will have the priority. Each part will contain the species fastened to paper, or not if preferred, and each species will have a printed note giving the name of the plant, the spot wherefrom it comes, and various literary and critical observations. The copies which may remain over, after the contributors have been supplied with their parts, will be sold.

Delicate filaments of living matter flow out from the protoplasm of many one-celled animals, and exhibit remarkable movements. Similar thread-forming phenomena are said, by Gwendolen Foulke Andrews, to appear when the protoplasm of developing starfish and sea-urchin eggs are examined under very high powers; they are termed by the author the *spinning* activities of the living substance (*Journal of Morphology*, February 1897, vol. xii.). It is claimed that the filaments are projected from normal Echinoderm eggs; and that they are concerned in the formation of the egg membrane. The facts appear to point to a physiological drawing together of the cells by the filaments, rather than to any physical and chemical "cyto-tropismus." Also, a physiological, rather than a physical, reaction to mechanical stimulus of pressure or shaking is indicated; in fact, the cause of the spinning activities is held to be physiological rather than physico-chemical. For the living substance, cell-walls apparently do not a prison make, for we read: "Whatever may be the significance of the cell-wall in the development of these eggs, it surely cannot be thought a separator, in either a physical or physiological sense, of the cell contents from other portions of the common mass." Or, as put in other words, "the peripheral substance of eggs and cells is freely protoplastic, despite its appearance under less magnification of being a smooth and stable pellicle."

The following lectures will be given during May at the Royal Victoria Hall, at 8.30:—May 4, "Mountains of Skye," by Dr. T. K. Rose; May 11, "More about Röntgen and other Rays," by Prof. A. W. Porter; May 18, "Travel and Adventure in South Africa," by Mr. F. C. Selous; May 25, "Growth of the Colonies in the Queen's Reign," by Mr. O'Donnell.

We have received vol. xl. part v. and vol. xxx. part iv. of the Annals of the Astronomical Observatory of Harvard College. The first of these gives the observations made at the Blue Hill Meteorological Observatory under the direction of Mr. A. Lawrence Rotch, and contains an appendix, including summaries of observations for the lustrum and decade, a discussion of them, and a bibliography. The second of these volumes deals with a discussion of the cloud observations by Mr. H. Helm Clayton. This is described somewhat in detail, and several interesting plates showing, for instance, the average cloudiness during cyclones, anti-cyclones, their movements, and numerous annual and diurnal curves, illustrating average cloudiness at Blue Hill.

Four common species of the family Dermestidæ have become vegetarians; and their conversion forms the subject of a paper in *Bulletin* No. 8 (New Series), of the U.S. Department of Agriculture (Division of Entomology). Cyclopædias and text-books inform us that the members of this well-known family feed upon dried animal substances. The depredations of certain species on leather, hides, and dried meats; of others on carpets, furs, and woollen goods; and of still others on dried insects, and other "objects of natural history" are, unfortunately, too well known to require further comment. Within recent years, however, several household dermestids have been suspected of living in the larval condition upon vegetable substances, and the charge of having vegetarian proclivities has now been brought home to four species, viz. *Attagenus piceus*, or black carpet beetle; *Trogoderma tarsale*, a bad cabinet pest; *Trogoderma sternale*, and *Anthrenus verbasci*. The first-named is found guilty of feeding upon flour and meal; the second revels in fiery-red pepper; and the third species appears to be able to thrive on such laxative substances as castor-beans and flax-seed. The change from a natural animal-feeding habit to a vegetable one is attributed to altered environment.

We have just received the Report of the U.S. National Museum, under the direction of the Smithsonian Institution, for the year 1894. About two hundred pages of this report are devoted to reviewing the work accomplished in the various scientific departments of the Museum, and general administrative matters; the remaining five hundred pages are taken up with most valuable papers describing and illustrating collections in the Museum. These papers have already been referred to (p. 469), and we need only now give expression to the gratitude which all men of science feel towards the Smithsonian Institution for the many ways in which it extends knowledge among men.—Another recent publication by the Smithsonian Institution is "A Recalculation of Atomic Weights," by Prof. Frank W. Clark. This fifth publication in a series on "The Constants of Nature" comprises a full discussion and recalculation of atomic weights from all the existing data, and the assignment of the most probable value to each of the elements. The first edition was published in 1882. The enormous mass of new material which has since become available has been assimilated and combined by Prof. Clark with the old data in the present edition of his most handy work.

Dr. S. Schönland's report on the Albany Museum, Grahamstown, during the year 1896, shows satisfactory progress. Large additions have been made to the publicly exhibited collections, and the collections formed for purely scientific purposes have grown even more rapidly. A sum of three thousand pounds was voted by the Cape Parliament last year towards the cost of a new building to accommodate the increasing number of specimens. Plans have been prepared for the new museum, and it is hoped that Parliament will make a further grant to enable them to be carried out. The alarming spread of insect pests in the Eastern Province occupied the attention of the Committee of

the museum for some time, and the conclusion was arrived at that it was largely due to the wholesale destruction of insectivorous birds. Steps have therefore been taken to protect useful birds and their eggs. Dr. Schönland has established a small private botanic garden for South African plants. He remarks that he was driven to this step, because there is, unfortunately, no public garden in Cape Colony for the study of the South African flora. The relics of pre-historic South African races were also studied during the year, some interesting finds being obtained from three caves at King's Quarry, Grahamstown. A number of peculiar drawings on rocks in Bechuanaland were examined by Dr. Schönland. Although there was no decisive evidence to show that they were the work of Bushmen, the facts obtained certainly point to that conclusion.

AMONG noteworthy articles and publications which have come under our notice during the past few days are the following:—"Storms and Weather Forecasts," by Prof. Willis L. Moore, in the *National Geographic Magazine* (March). Twenty-six full-page plates, illustrating the weather characteristics of the United States, accompany this article.—"Neural Terms, International and National," by Prof. Burt G. Wilder, reprinted from the *Journal of Comparative Neurology*, vi. (December 1896). A critical treatise on the principles and practice of anatomical nomenclature, with special reference to the brain.—"Zusammenstellung der Ergebnisse neuerer Arbeiten über atmosphärische Electricität," by Profs. J. Elster and H. Geitel (Jahresbericht des Herzogl. Gymnasiums zu Wolfenbüttel, 1897). Some years ago (1891), Profs. Elster and Geitel brought together, in the yearly report of the Wolfenbüttel Gymnasium, the investigations which had been made on atmospheric electricity. They have now collated the large amount of work done by others and themselves during the past six years. Their review is thus a valuable summary of the progress made in an important branch of scientific inquiry.—The *Procès-verbaux* of the International Committee on Weights and Measures, for the year 1895, and the *Comptes rendus* of the meetings of the second conference on weights and measures, held in Paris in 1895.—On the Artificial Production of certain Organic Forms, and the Manner in which they are Produced," by the late Mr. George Rainey (St. Thomas's Hospital Reports, vol. xxiv.). This paper is reprinted from the *Medical Times and Gazette* of 1868, and all practical workers in experimental physiology will be glad to have their attention drawn to it. Mr. W. W. Wagstaffe contributes a brief introduction to the reprint.—"A Summer Voyage to the Arctic," by G. R. Putnam (*National Geographic Magazine*, April). An account is given of a voyage to Umanak fiord, in the northern part of Danish Greenland, and several hundred miles within the Arctic circle. The magnetic observations made during this expedition are described by Prof. G. R. Putnam in the March number of *Terrestrial Magnetism*.—"Contributions towards the Bibliography of Photography in Colours," by Thomas Bolas (*Journal* of the Society of Arts, April 23). A valuable descriptive list of what has been published on colour photography since 1810.—A full and very appreciative obituary notice of the late Prof. Sylvester is contributed to *Science* of April 16, by Prof. G. B. Halsted, who was his first pupil in the Johns Hopkins University.—In a Catalogue of Mathematical Works offered for sale by Messrs. Dulau and Co., mathematicians will find many rare and valuable papers. The catalogue runs into 178 pages, and the names of authors are arranged in alphabetical order.

IT is well known that when carbon is used as anode in the electrolysis of electrolytes from which oxygen is evolved among the products of decomposition, the carbon is attacked more or less rapidly. This is due partly to chemical action, partly to mechanical disaggregation. Mr. Alfred Coehn contributes an interesting note on this important subject to the *Zeitschrift für Elektrochemie* for April 5. The phenomena observed when dilute sulphuric acid is electrolysed with platinum kathodes, and carefully purified arc-lamp carbons as anodes, depend on the concentration of the acid. When an acid containing 500 volumes of water to one volume of concentrated sulphuric acid is used, the liquid gradually becomes dark brown; with equal volumes of acid and water, it remains colourless; with intermediate concentrations the depth of colour is intermediate At higher temperatures the mechanical destruction of the carbon diminishes, and even the stronger acids become brown. The author has attempted to determine the electro-chemical equivalent of carbon, employing acid containing equal volumes of strong sulphuric acid and water, at a temperature of 100° C. Under these circumstances the mechanical destruction of the carbon appears to be small compared with the chemical attack. While 4·0085 grams of copper were deposited in a copper voltameter, the carbon anodes lost 0·4476 and 0·4537 grams respectively, from which the value of the equivalent is 3·5. In a second series of experiments, in which the concentration of the acid was varied considerably, and the fragments of carbon mechanically lost were collected, weighed, and deducted from the total loss of weight of the anodes, values were observed varying from 2·7 to 3. The author promises further details of the experiments in a future communicaton.

THE additions to the Zoological Society's Gardens during the past week include a White-fronted Capuchin (*Cebus albifrons*) from Venezuela, presented by Sir William Hoste, Bart.; two Pin-tailed Sand Grouse (*Pterocles alchata*) from India, presented by Mr. W. H. St. Quintin; a Black-headed Gull (*Larus ridibundus*), British; two Rufous-necked Weaver Birds (*Hyphantornis textor*) from South Africa, presented by Mr. W. H. Dobie; a Cactus Conure (*Conurus cactorum*) from Brazil, presented by Mrs. A. G. Scorer; a White-crested Touracou (*Turacus corythaix*) from South Africa, deposited; a Crowned Lemur (*Lemur coronatus*) from Madagascar, a —— Spider Monkey (*Ateles variegatus?*) from South America, three Double-banded Sand Grouse (*Pterocles bicinctus*) from Senegal, purchased.

OUR ASTRONOMICAL COLUMN.

PECULIAR STELLAR SPECTRA.—Harvard College Circular (No. 17) continues the list of stars the spectra of which have been designated as "peculiar."

The table contains no less than nineteen stars, but we will confine ourselves in the summary to those of smaller southern declinations.

Designation.	Approx. R.A. 1900.	Approx. Decl. 1900.	Mag.	Description.
	h. m.			
A.G.C. 9313	7 14·5	−24 47	4·6	Peculiar. 30 Can. Maj. Resembles ζ Puppis.
A.G.C. 10182	7 43·9	−25 42	5·3	Hβ bright. o Puppis.
	13 31·1	−55 58		Peculiar. Variable.
A.G.C. 22640	16 39·2	−46 54	7·4	Bright band, wave-length about 4700.
	20 8·5	−44 43		Peculiar. Variable.
A.G.C. 29191	21 11·5	−39 15	7·3	Peculiar.
A.G.C. 31272	22 55·0	−23 4	8	Peculiar.

In the notes it is mentioned that the third star in the above list "may resemble" that of ζ Puppis, since it contains two bright lines which may coincide with the lines having wave-lengths 4633 and 4688. ζ Puppis, 29 Canis Majoris, 30 Canis Majoris, and this star may form a subdivision of Type V. All these stars are near the central line of the Milky Way.

The fifth star was noted by Dr. Stewart as "bright-line star (faint)" on a Bruce photograph. An examination by Mrs. Fleming has indicated that the star is variable and the spectrum peculiar.

The Planet Mercury.—The length of the period of rotation and the physical features of the inferior planet Mercury have formed the subject of a recent investigation by Mr. Percival Lowell, the results of which are contributed to the *Astr. Nach.* (No. 3417). The conclusion he has arrived at, from a considerable amount of research, is that this planet rotates once on his axis in the course of its circuit round the sun. As regards the markings on the planet's disc, he describes them as being perfectly distinct, absolutely defined, and always visible. They are narrow dark lines, but not so fine as they appear to be. Their relative positions are permanent. Their positions from hour to hour do not change, thus eliminating any question of a short period of rotation. The permanency of the markings indicates the absence of clouds and other obscurations over the surface of the planet. With regard to an atmosphere, we are informed that there are no positive signs, either direct or indirect. There is, however, negative evidence against the presence of any perceptible atmosphere—namely, the low albedo of the planet, and the great contrast of the surface markings. Unlike Mars, the planet's surface is colourless, and there seems, further, to be no change in the markings, which might indicate presence of seasonal effects. The observations made at the Lowell Observatory are thus in accord with what would be expected, considering the isochronism of the orbital and axial rotations, and the small inclination of the axis to the plane of the orbit. Without an atmosphere, and therefore waterless, the visible surface of the planet may be looked upon, as Mr. Lowell remarks, as "one vast desert."

It may be remarked that M. Leo Brenner, who has also made some recent observations of this planet's surface markings, has, in a recent number of the *Astr. Nach*, come to a somewhat different conclusion. The spots, he says, are remarkably clear, and a comparison of drawings has indicated that the period of rotation of the planet is comprised between thirty-three and thirty-five hours, or in the mean thirty-four hours. It does not appear to be possible to admit a duration of eighty-eight days for the rotation period.

Nova Aurigæ.—Prof. W. W. Campbell publishes some spectroscopic notes in the *Astrophysical Journal* (No. 4, vol. v.), among which are some relative to the new star that appeared in 1892 in Auriga. The observed intensities of six of the principal bright lines up to October 6, 1896, were as follows :—

	Hγ	λ4560	Hβ	λ4960	λ5010	λ5750
1892 Aug. and Sept.	0·1	0·5	1	3	10	1
1894 May 8	0·1	0·3	1	3	10	0·4
1894 Sept. 7	0·1	0·2	1	3	10	0·4
1894 Nov. 28	0·1	0·1	1	3	10	0·3
1896 Aug. 15	—	—	1	3	10	0·1
1896 Oct. 6	—	—	1	3	10	0·1

It will be noticed that the bright lines 4360 and 5750 have gradually diminished in intensity, the latter being scarcely visible at the last observation. These lines, it may be remarked, were strong in the Nova, but faint in the old nebulæ. Their gradual disappearance indicates that the return of this Nova to the nebula stage has been reached, "it is now of the ordinary type of nebular spectrum, save that the lines remain broad, as they have always been described." When the question as to the actual visibility of the nebula after the spectroscopic evidence of its truly nebular character came to be inquired into, several observers found that its appearance was not like that of a star of the same magnitude ; while Prof. Barnard announced that the object was "really a bright nebula with a 10th magnitude nucleus." Prof. Campbell, estimating the magnitude of the Nova by comparing the length of its spectrum with that of a star of equal magnitude, came to the conclusion that "the focal image of Nova Aurigæ is stellar."

THE SIMPLON TUNNEL.

THE project of a tunnel through the Simplon has been so much discussed and so frequently abandoned, that one might almost doubt whether the scheme last suggested will ultimately prove effective. But the present plan has been brought to a more forward stage than on any previous occasion ; the requirements of interested Governments have been met, the pecuniary difficulties seem to have been overcome, and, finally, contracts have been signed with an eminent firm of engineers, whose name is a guarantee that what is undertaken will be performed. We may, therefore, confidently expect in a short time to hear that this arduous work has been commenced ; and it is scarcely premature to glance at the various problems, physical, mechanical and economical, that have had to be solved, or to express a hope that the solutions which have been offered, based as they are on varied experience, will prove adequate to cope with the many difficulties that will arise.

The economical problem can be easily dismissed. The advantages of the Simplon route are so patent, that the perforation of the mountain was suggested in the early days of railway enterprise, at a time when the difficulties that the Alps presented to continuous traffic were more fully apprehended than were the means by which those difficulties were to be surmounted. It is a very easy thing to put down on paper the number of miles that separate, say, London from Brindisi, and show that the train mileage is less by way of Simplon than either by Mont Cenis or Saint Gothard ; and yet both these routes have been opened to traffic before the most advantageous line has been begun. If we select some station, as Plaisance, on the eastern side of the Alps, and directly on the Brindisi route, we have the following distances, according to the course followed :—

From London, Calais, Paris, *Cenis* to Plaisance,
1438 km. = 894 miles.
From London, Calais, Bâle, *Gothard* to Plaisance,
1375 km. = 854 miles.
From London, Calais, Reims, *Simplon* to Plaisance,
1253 km. = 779 miles.

But this saving of distance, amounting as it does to near 8 per cent., does not express the whole of the advantag that a route through the Simplon would offer. This last tunn being at a much less elevation above the sea-level than eithe of the others, the speed of the trains would be greater, and n special precautions needed to ensure the safety in passing ov inclines rather steeper than are usually experienced on frictio railways.

The maximum height of the Simplon tunnel is 706 m.
,, ,, ,, Gothard ,, 1155 ,,
,, ,, ,, Mont Cenis ,, 1295 ,,
The Arlberg railway is the highest of all, being 1311 m.

To balance the economy of distance and small altitude, we have to consider the length of tunnelling necessary, and unfortunately the length required is in the inverse proportion to the conveniences of the route. The first-made tunnel, that of Mont Cenis, is 12,849 m. long, the Gothard 14,984 m., while that of the Simplon is computed at 19,731 m., so that the ratio of the first is to the third as 2 : 3.

The geological conditions have been well studied, and it will be interesting to compare the forecast framed from an examination of the external appearance of the mountain with the character and extent of the rocks actually encountered. On the south side, for a distance of about four miles, the principal rocks will be clay and mica slate with gneiss. In the central portion, extending over something like six miles, the boring tool will have to work its way through gneiss, alternating with mica schist, and limestone. On the northern side, towards the Rhone, slate and beds of gypsum will form the principal constituents ; and here, though the rocks may not be so hard as in the centre of the mountain, greater difficulty is anticipated owing to the extreme precaution that will have to be taken in protecting the sides of the tunnel. The direction given to the perforation will make the axis of the tunnel practically perpendicular to the various seams.

If the extent and hardness of the rock were the only physical difficulties with which the engineers had to contend, doubtless the boring would have been attempted long since ; but another, and a greater obstacle has to be overcome in the temperature of the rocks themselves. To excavate under a mountain is to some extent comparable with sinking a mine ; and recalling the comparatively low altitude at which the tunnel is to be constructed, and the consequent height to which Monte Leone will tower above it (more than 2000 m.), it is evident that a pretty deep mine is contemplated. We are going to learn something of the internal heat of the earth at a considerable distance from the surface. One can make a pretty shrewd guess at what these temperatures will be, from previous experience in the Cenis and Gothard tunnels ; and evidently the advantage of keeping the tunnel nearer to the sea-level, which will facilitate traffic, is accompanied with the disadvantage of having

a greater mass overhead, and consequently greater heat. In the case of the Gothard, an increase of depth of 44 m. occasioned a rise in the temperature of 1° C. On this hypothesis, which is of course rough and approximate, in the middle of the work the thermometer will read about 40° C. In the Cenis the maximum temperature reached was 29° C.; but the workmen had to submit to this temperature for a short time only. In the Gothard the temperature of 31° C. had to be contended with for a long distance, and the sufferings were proportionately severe. Anæmia and kindred diseases played havoc with the work-people. Some 60 per cent. of the workers, it is reckoned, were attacked; and to prevent a similar disaster in the present undertaking, another set of problems, dealing with ventilation and sanitation, had to be considered as part of the entire mechanical difficulties that present themselves.

The lines along which the main engineering problem has been solved are tolerably well known. The scheme contemplates the construction of two parallel tunnels, whose axes will be separated by 17 metres. These two parallel roads will be connected at regular intervals by transversal galleries leading from one to the other, capable of being closed at will by air-tight doors. Only one of the main tunnels will at present receive its final dimensions, and be fully finished for traffic. The breadth will be 5 m., and the height above the sleepers 5·5 m. These dimensions will permit only a single line of rails to be laid, and provision is made in the middle of the tunnel for a siding 400 m. long, so that two trains may pass in opposite directions. The object of the second tunnel, which will have a section of eight square metres, is mainly to ensure sufficient ventilation, and, indeed, to make the work in the main gallery possible. It was this ingenious thought, of carrying along simultaneously the two galleries, which has brought the perforation of the Simplon within the range of possibilities. This suggestion is due to Herr Brandt, of the firm with whom the contract has been placed. The distinguishing feature of this proposal is that it will ensure a current of air passing through the entire system of the tunnels. Evidently, if ventilating apparatus be placed at the entrance of either gallery, a current of air can be forced through one tunnel, through the transverse gallery at the end of the working (all the intermediate openings being closed), and out through the other tunnel. If it be objected that the construction of the second gallery is a very expensive method of supplying fresh air to the workpeople, the answer is that, without some such means, the perforation is found to be impracticable. But the expense is not so great as it seems, because the second gallery can at no very great additional cost be made available for traffic when this increases to such an extent as to make the single line first laid insufficient. It is proposed to supply through this supplementary tunnel 50 cb.m. of air per second, by means of a current moving with the velocity of 13 miles an hour. Such a supply is far in advance of the quantity available at the Saint Gothard workings, and is to some extent founded on the amount that is found necessary to ventilate the Mersey tunnel. In this latter case the supply of fresh air, which no one who has made the journey from Birkenhead to Liverpool would say is excessive, is, it is true, four times greater than the quantity that will be pumped into the Simplon passage; but the number of trains that pass in a day is considerably more, under the Mersey, than will be the case in the Simplon passage. Such a current may, therefore, be sufficient for the workmen, and will certainly tend to reduce the high temperature; but the engineers will not trust to this means alone, to make the interior of the cutting endurable. Recourse will be had to the distribution, throughout the workings, of fine water-dust under considerable pressure. If the water, as it is hoped, can be delivered at the rock face at a temperature of 12° C., it can be employed with the happiest effect. Experiments made at Winterthur, before a committee of experts, proved that an air temperature of 40°—50° C. could be lowered to 15° by employing a water-dust of 12° C. under a pressure of five and a half atmospheres. When higher pressures are available a still more marked result is produced, and the abundant supply of water at both ends of the tunnel will permit this method to be tried under very favourable circumstances.

This large supply of water, from the Rhone on the north side, and from Italian streams on the south, very fortunately permits the use of hydraulic machinery as a means of economically working the boring apparatus. In other works of similar character, compressed air has been the agent employed, against the use of which some objections have been urged. We have here, therefore, the means of comparing the efficiency of the two methods, both in the operation of cutting through the hard gneiss rock, and the effect on the health of the operators, on whom the escape of the compressed air is said to work disadvantageously. On the Arlberg, the natural surroundings of which are comparable with those to be met on the Simplon, the Brandt hydraulic perforating machine has given great satisfaction. It is contended by its supporters that, in a work of such magnitude, where the power has to be supplied from a great distance, that hydraulic transmission is to be preferred to all other, because with it the loss of force is the least. From actual experiment on gneiss rock, it has been shown that a perforation 1 m. deep and 70 mm. diameter can be bored in 12 to 25 minutes, and that consequently a daily advance of 5·85 m. can be reckoned upon. That M. Brandt has the greatest confidence in his invention and in his methods is shown by the fact that, in the contract which he has signed, he is willing to submit to a fine of 5000 francs a day in case the work is not completed in the five and a half years he allows himself. The total cost of the entire construction is computed at less than 3,000,000*l*. It is interesting to compare the rate of progress and cost of construction of the three tunnels which will compete for the Trans-Alpine traffic. In the case of the Mont Cenis tunnel, which represents the state of mechanical science some thirty years since, a year, approximately, was required to complete each kilometre at a cost of six millions of francs. The Saint Gothard, about ten years later in date, proceeded twice as rapidly, while the cost of construction dropped to four million francs per kilometre. Herr Brandt, however, proposes to complete four kilometres per annum, at the same time reducing the expense per kilometre to one half that of the earliest tunnel. One may well wish that this sanguine estimate will be justified.

ON THE COLOUR AND COLOUR-PATTERNS OF MOTHS AND BUTTERFLIES.

A PAPER by Mr. Alfred Goldsborough Mayer, on "The Colour and Colour-Patterns of Moths and Butterflies" (*Proceedings* of the Boston Society of Natural History, vol. xxvii. No. 14, pp. 243–330, March 1897), is a rather elaborate discussion of a subject which has lately attracted much attention; but though Mr. Mayer has made some interesting experiments and observations, his results are neither so novel nor so important as he claims them to be. One of the most interesting parts of the paper is the account of the development of wing-colours during the pupal state, a summary being given of previous researches, supplemented by a series of new observations on common species of American moths and butterflies. The result arrived at is, that the wings are at first transparent, then white, then drab or dusky yellow, while all the purer and brighter colours arise later on. This is what might be expected from the general distribution of colour in lepidopterous insects, and has been indicated by Dr. Dixie and other writers as probable.

Some ingenious experiments were made for the purpose of ascertaining whether the wing-scales were of any use in giving a greater hold on the air. The wings, with and without scales, were attached to a delicate pendulum, but no measurable difference in air-friction was found. Neither do the scales perceptibly strengthen the wings, hence it was concluded that they have been developed solely as colour-producing organs of use to the various species.

A considerable space is devoted to the development of the colour-patterns of the Danaoid and Arcræoid Heliconidæ and the phenomena of mimicry. These are illustrated by four coloured plates intended to show the markings of a large number of species. These plates do not represent the insects themselves, but are "projected by Keeler's method" on rectangles of uniform size, which are supposed to afford more accurate means of comparison. This will seem to most naturalists to be a great mistake. It not only renders the patterns of the most familiar species almost unrecognisable, but it introduces many possibilities of error in the process of projection which even a comparison with the species represented may not enable us to detect. In the case of mimicking species it has the further disadvantage of obscuring differences of outline, and by irregular distortion giving undue prominence to what may be very slight differences in the actual species. In many mimicking species there is a wonderful similarity of

general effect combined with considerable differences of detail, and by the process of "projection" these differences of detail may be exaggerated while the general similarity is obscured.

While accepting Fritz Müller's explanation of the mimicry of protected species by each other, and as also affording the only intelligible reason for there being only two types of colour-pattern in the whole 400 species of the Danaoid Heliconidæ, he says that "unfortunately no *direct* experiments have been made on the feeding habits of young South American birds." But in view of the careful experiments of Prof. Lloyd Morgan on a variety of young birds this is hardly necessary, as it is proved that they have in no case any instinctive knowledge of what is edible or distasteful, while they acquire the knowledge by experience with extreme rapidity. Like many other writers on the subject who have recently criticised and rejected the theory of warning colours as indicating inedibility, Mr. Mayer does not distinguish between the *habitual* and the only *occasional* enemies of protected insects. Thus he refers to the experiments of Beddard, showing that toads will eat any insects whatever; but it is quite certain that toads are not very dangerous enemies to either butterflies or their larvæ, nor probably are marmosets, which are also general feeders. There is quite sufficient evidence to show that insects with warning colours *are* rejected by most insectivorous birds and lizards, which are certainly the most general and most dangerous devourers of insects both in the larva and winged state, and these facts, taken in conjunction with the experiments of Prof. Lloyd Morgan, afford a firm foundation for the whole theory of warning colours and mimicry. A. R. W.

THE PRIMATE BRAIN.[1]

THE comparative study of the convolutions of the brain surface in man, apes and monkeys, may be said to have been founded by Gratiolet, who mapped out the fissures in the lower monkeys, traced the patterns upwards through the apes to man, and invented a system of names for the convolutions. In recent years this study has received impulse from two distinct causes: on the one hand, the greater opportunity of examining the brains of the higher apes; and, on the other, the attempt to locate in the convolutions definite functions has led to experiments being conducted, by physiologists and psychologists, upon the brains of monkeys. A great variation in the convolutions of species of monkeys and of apes has been thereby shown to exist, and more accurate data have been rendered available for a true morphological comparison with those of man; and although the subject has, to a very great extent, been attacked from a physiological standpoint, yet the morphology of the convolutions has received increased attention during the past few years, notably at the hands of Dr. Cunningham, whose careful and extended work on this subject covers a good deal of the ground opened up in the present memoir, which deserves a place alongside that of the Dublin anatomist.

The publication of Dr. Parker's work, which was communicated verbally, to the Academy of Philadelphia, as long ago as 1890, has been delayed till last year, owing to a variety of circumstances—amongst others, the death of the author in 1892. After an introduction dealing with the scope and aim of the memoir, there follows an interesting historical survey of the observations and opinions of the chief writers on the subject. The author then tabulates the names of the fissures and convolutions applied to the human brain, with their synonyms as employed by each author. This table will be of considerable value to students of the subject, as will be the historical survey.

How are these convolutions and furrows on the surface of the brain brought about? What is the cause of the gyrencephalous condition? This is still a matter of controversy. To this question two chief, but opposing answers have been suggested, each supported by equally competent authorities. The one school looks on these convolutions as due to the effect of pressure of the slowly growing skull on the more rapidly growing brain. The opposite school believe the cause to be innate—that is to say, the convolutions owe their origin to differential growth in certain definite regions of the brain surface itself. Dr. Parker combines these two opposing views: believing that certain "fundamental fissures" are produced by mechanical causes, whilst others owe their origin to morphological processes of growth in the brain substance; the fissures, of course, representing lines of retarded growth. During early development, it is the brain which modifies the shape and structure of the skull, rather than the reverse; ultimately, as the skull grows more rigid, its influence is shown in the increasing tortuosities of the folds.

The development of the human brain is traced out, so far as is necessary to explain the author's views, and the various stages are compared with the adult brain of monkeys. At the age of three months the fœtal human brain consists of three lobes, which he terms the "occipito-frontal," "occipito-temporal," and "occipital." It does not immediately appear evident why the author employs compound names for the two former lobes, unless it be to insist as strongly as possible upon the fact that there is no such thing as "parietal lobe," at any rate as a morphological equivalent of the others. The "island of Reil" is not homologous with a "lobe," but is developed at the bottom of a depressed area, the *fossa sylvii*. Each of the three lobes contains a portion of the lateral ventricle; each will exhibit a similar, and symmetrical series of furrows. He points out here, as elsewhere, that the "occipital" lobe, developed as it is round the posterior cornu of the lateral ventricle, is peculiar to the Primates.

During the third month a certain number of "temporary furrows" make their appearance on the surface of the hemispheres; they radiate from the region of the sylvian fossa, and when viewed from the mesial surface, lines drawn through all but those in the occipital lobe meet at a centre which lies in the cerebral peduncle: and the angle included between any two neighbouring lines is constantly 60°, or thereabouts. This fact he makes use of in considering the causes concerned with the production of these fissures, which he attributes to pressure between brain and skull.

But, as is well known, these temporary fissures disappear, and the brain again becomes smooth for a short time at about the fifth month; and he lays great stress on this smooth brain, with its three lobes, a sylvian fissure, a calcarine fissure, and "mesial arched fissure." The author regards this stage as the fundamental plan of the Primate brain; indeed, this is essentially the marmoset's brain enlarged. Later on, new fissures appear, and he recognises, in addition to the (1) fundamental or primary fissures, just mentioned, the (2) secondary fissures, (3) sulci of Pansch, mere vegetative repetitions of (2); (4) sulculi, which are inconstant, and (5) rami, which are the branches of (2) or (3). The mesial arched fissure gives rise to the callosal and the hippocampal fissures; each of which, with the calcarine, is similarly related to one of the three primary lobes.

The occipital lobe next becomes definitely marked off from the rest by two fissures, a dorsal and a ventral, constituting the "primary occipital arch." The dorsal one is the "parieto-occipital" or "perpendicular fissure" of monkeys. The mesial ends of these are symmetrical with regard to the calcarine. These fissures, again, are regarded as being due to pressure.

This stage represents the characteristic Simian brain (including that of man).

Parker disagrees with the usual view, that the *fissure of Rolando* is a primary fissure; nevertheless, it is certainly characteristic of the primate brain, for it occurs in no other order. He explains the fissure in an ingenious manner, by reference to a lemur's brain, in which there are two longitudinal fissures extending along the fronto-occipital lobe; a part of the upper one is supposed to become vertical. But no ontogenetic evidence is forthcoming for this view, which would lead us back readily to the condition of a carnivore's brain.

It is impossible to give briefly his many interesting suggestions as to the homologues of the frontal and parietal convolutions; but special interest will be taken in his account of the occipital convolutions, for these have always troubled anatomists, who have until recently regarded them as being more or less irregularly arranged, and consequently have neglected them. Parker endeavours to show that they can be reduced to order, especially if the development of the "plis de passage" or "annectant gyri" be taken into account. These rise up, as I have shown in discussing the brain of the chimpanzee "Sally," and as others have also shown, from the bottom of fissures; so that in one brain they may be hidden, in another they come to the surface and divide single fissures into two. Parker says: "The typical fissures represent the lines of least resistance to the differential action of the pressure forces.

[1] "Morphology of the Cerebral Convolutions, with special reference to the Order of Primates." By Andrew J. Parker, M.D. *Journ. Acad. Nat. Sci. Philadelphia*, 2nd series, vol. x., 1896, pp. 247 to 362; with fifteen plates and several figures in the text.

. . . As development proceeds, and the skull begins to assume a more fixed and rigid shape, new conditions and relations of the growth forces take place, as a result of which those portions of the cerebral surface lying in the depths of some of the fissures, originally produced by depression, are placed under new dynamical conditions; instead of being situated as formerly along the lines of resolution of greatest pressure and least resistance, they become centres of relatively greatest growth force as compared with the resolution of pressure forces." Hence they rise up as annectant gyri. To these interesting, and at one time puzzling, features he devotes some pages.

He gives a very brief, and second-hand, account of the convolutions in Carnivora and Ungulata, rightly insisting that it is impossible to homologise these fissures, one by one, with those of Primates' brains; for, even between ungulate and carnivore, it is only possible to compare groups of fissures. This fact is gradually becoming more and more fully recognised; and in mounting a series of brains for the Oxford Museum, I have purposely indicated the fissures in the ungulate, for example, and the Primate brain, by means of entirely different sets of colours. There is a type of convolution for each order, these types being derived, not one from another, but independently for a smooth-brained condition; a view which accords with palæontological evidence. Nevertheless, there is more community between the Ungulata and the Carnivora, in this matter, than between other groups.

Finally, the author discusses the "Mechanics of the formation of cerebral fissures," and brings to bear on the subject (*a*) the theory of the formation of films in soap-bubbles, propounded by Plateau; and (*b*) the facts of surface tension as put forward by Maxwell. This part of the paper is illustrated by numerous formulæ and diagrams; but I imagine most anatomists will pass these by. If for surface tension of films we substitute the pressure forces produced by cerebral swellings aggregating round certain centres, then the peripheries, meeting each other within a confined space, produce the lines of fissuration.

The memoir, interesting as it is, would have been rendered more valuable by the addition of a bibliography; references are, indeed, given here and there in footnotes, but they are scarcely worthy of the work.

The figures, again, copied as many of them are from various sources, are variously lettered; there is practically no "explanation" of plates, and some of the figures, which are mere outline drawings without shading, represent the brain in oblique directions, which it is very difficult to follow, as no indication of these directions is given in the list of figures.

W. B. BENHAM.

LECTURE-ROOM DEMONSTRATION OF ORBITS OF BODIES UNDER THE ACTION OF A CENTRAL ATTRACTION.[1]

NOT remembering to have seen any attempt to show experimentally in the lecture-room the motion of bodies acted on by a central attractive force varying inversely as the square of the distance in elliptic, parabolic and hyperbolic orbits, I have made a few experiments with a view of determining how well these curves could be imitated by the motion of a small steel ball around a magnetic pole. The results were so good that I feel warranted in making them known, and believe that the experiment may be found useful in making more cheerful that portion of the course usually rather destitute of pyrotechnics.

The apparatus used was very simple, consisting of a circular glass plate about 40 cm. in diameter, with a small hole in the centre, through which projected the somewhat conical pole-piece of a large electro-magnet (Fig. 1). The surface of the plate was smoked, and it was made level as nearly as possible, the axis of the magnet being of course vertical.

A small, highly-polished ball of steel about 5 mm. in diameter (from a bicycle bearing), when projected across the plate, traced its path in the soot, and left a permanent record of its motion.

Under these conditions gravity exerts no direct influence on the motion, and we have only the initial velocity and the central attractive force to deal with, together with the loss of velocity due to friction. There are several other circumstances which make the conditions unlike those existing in the case of two gravitating bodies in space, and, taking everything into consideration, it is quite surprising what good results were obtained.

The ball was blown out of a short piece of glass tubing held in the plane of the plate with varying initial velocities, and curved orbits obtained, which were, at least, good imitations of the ellipse parabola and hyperbola.

Fig. 2 is a photograph of a plate showing all three forms, the white spot in the centre being the hole occupied by the magnet pole; the arrows indicate the direction of the motion.

No. 1 was produced with low initial velocity, and is a very fair represention of an ellipse, with the attractive force in

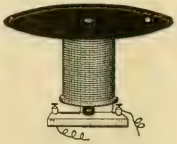

FIG. 1.

one focus. The loss of velocity due to friction caused the ball to "fall into the sun" after completing one revolution, a one year's existence of the system.

On another trial an ellipse (*spiral*, strictly speaking) was obtained that was almost re-entering, the miss being not more than a couple of millimetres, while in the one figured it was nearly a centimetre.

The right-hand branch of No. 2 resembles a parabola, and was produced by a somewhat higher initial velocity. It will be noticed that the ball moved to its perihelion position in a path rather like a hyperbola, and on rounding the pole, its velocity having been diminished somewhat, moved off in a

FIG. 2.

parabola. It would be more exact, probably, i. we called this curve an ellipse of great eccentricity, since the conditions governing the formation of a parabolic orbit would be difficult even to approximate.

No. 3 and 4 are hyperbolæ, produced by still higher initial velocities.

None of the orbits shown in the figure are as perfect as some that have been obtained by accident on other plates. It is very difficult to make a plate showing all three forms with only four or five trials, as the velocity has to be nicely adjusted; consequently, the curves shown in the figure must not be taken as samples of the best that can be produced by a large number of trials.

[1] Reprinted from the *Physical Review*, with supplementary note by the author.

The hyperbola is, of course, the easiest to produce, and the parabola the most difficult. Some device for regulating the initial velocity and aim would be conducive to more uniform results.

Polarisation of the steel ball is apt to give trouble, and I have obtained some repulsion orbits where the ball turns back before reaching the centre, which are very pretty, but not desirable when one is trying to illustrate central attraction. Soft

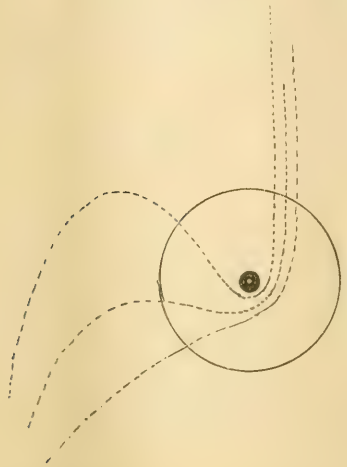

FIG. 3.

iron balls would be preferable to steel on this account; but they are not on the market, so far as I know, and the others answer the purpose well enough.

[*Supplementary Note.*—With a very powerful Rhumkorff magnet, belonging to the Massachusetts Institute of Technology, I have caused the ball to gyrate in a vertical plane about the poles, notwithstanding the perturbating influence of gravity. This elimination of the supporting plane makes the conditions

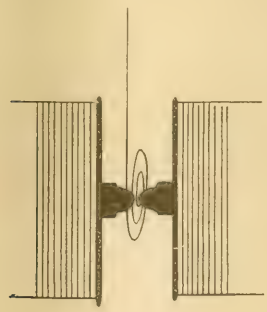

FIG. 4.

a little more like those existing in the case of plantetary bodies moving in space; but the motion is so rapid that it is difficult to see the form of the curve, and no permanent record is left: moreover, the curves are distorted by the downward pull of gravity.

The two conical pole-pieces of the magnet were brought close together, creating a very intense field, and the ball was dropped from elevations varying from six inches to a couple of feet at different distances from the vertical plane joining the poles. Usually the ball flies either directly to the poles, or moves in a path similar to some one of those shown in Fig. 3 (the pole being seen end on); but on several occasions I have succeeded in causing it to perform two or three complete revolutions, as shown roughly in Fig. 4.] R. W. WOOD.

UNIVERSITY AND EDUCATIONAL INTELLIGENCE.

CAMBRIDGE.—Mr. Sidney Colvin has been appointed by the Council of the Senate a Trustee of the British Institution Scholarship Fund, in the room of the late Prof. Middleton.

The subject for the Adams Prize for 1899 is "The Theory of the Aberration of Light." The prize is open to all graduates of the University. Essays must be sent to the Vice-Chancellor by December 16, 1898. The value of the prize is about 200*l*.

Sixteen candidates have passed the examination in Sanitary Science, and will receive the University's diploma in Public Health.

The annual prize for an essay on an archæological subject offered by Newnham College has been this year awarded to Miss R. E. White (first class, Classical Tripos, 1895); the subject was "Women in Egypt under the Ptolemies."

It is understood that the syndicate on degrees for women, whose report was referred back to them for reconsideration, have agreed to adhere to their recommendations. The voting on the scheme in the Senate is expected to take place about May 20. An active canvass for and against their proposals is being conducted by Committees in Cambridge and London.

IT has been decided to transfer the administration of the grants to schools in Scotland for science and art to the Scotch Education Department. The details of the transfer will be a matter of departmental arrangement.

THE Legislature of the State of New York has passed a Bill authorising the appropriation by New York City of two and a half million dollars for the purpose of erecting the new public library to be built on the corner of Fifth Avenue and West Forty-second Street, and the Mayor has approved the Bill; so that the city is pledged to execute the work.

THE following gifts and grants to educational institutions in the United States are announced in *Science*:—The Sheffield Scientific School of Yale University receives 25,000 dollars by the will of Mrs. Sarah Van Nostrand.—The department of natural history of Vassar College will receive about 25,000 dollars through the settlement of the will of the late Jacob P. Giraud.—A Bill before the Texas Senate appropriates for the State University 35,000 dollars for 1897 and 85,000 dollars for 1898, and in addition 42,000 dollars annually for the medical department.

SOCIETIES AND ACADEMIES.

LONDON.

Royal Society, April 8.—"The Production of X-Rays of Different Penetrative Values." By A. A. C. Swinton. Communicated by Lord Kelvin. Received March 24.

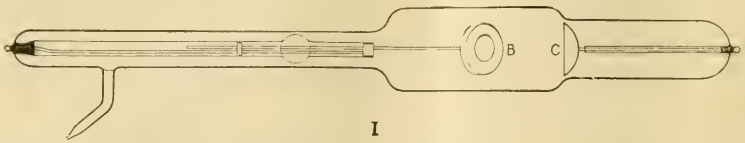
If the X-rays coming from a focus tube of the ordinary type be observed with a fluorescent screen during the process of exhaustion, the penetrative value of the rays is found to change as the exhaustion proceeds. At less than a certain degree of vacuum, no X-rays are produced. As the vacuum increases, X-rays commence to show themselves, but of a quality that will do little more than penetrate the backing of the screen. At higher vacua the rays become more penetrative, and show the shadow of the bones of the hand. The point is next reached when the flesh of the hand is very transparent, while the bones are still quite opaque. At higher vacua than this, the bones become more and more transparent, till at length, at the very highest vacuum at which the discharge will pass, the bones become nearly as transparent as the flesh, while the whole hand throws but a very faint shadow on the screen.

Similar effects can be produced with a constant vacuum by gradually increasing the power of the Rhumkorff coil, or by varying the resistance of the tube by means of a magnetic field, the X-rays being most penetrative with great electrical power

and high resistance in the tube, and least penetrative with low electrical power and low resistance.

The author has further found that it is possible to vary the penetrative value of the X-rays produced by a focus tube, by simply altering the distance between the kathode and anti-kathode.

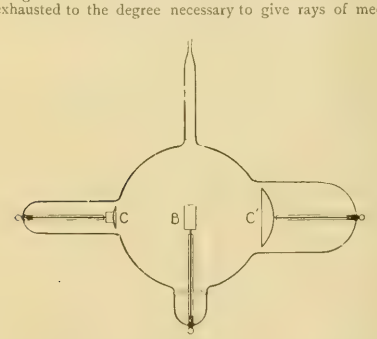
Fig. 1 shows such a tube, in which the anti-kathode B of aluminium, faced with platinum, is connected to the anode terminal by a sliding steel rod, so that it can be moved along the axis of the tube; and the distance between the kathode C and the anti-kathode B varied from 1 to 3 inches. With such a tube, exhausted so as to give X-rays of medium penetrative value, with the anti-kathode midway between its two extreme positions, if the anti-kathode be now placed nearer to the



I

kathode, the X-rays immediately become of a higher penetrative value, just as though the vacuum had been increased; while again, when the anti-kathode is moved in the opposite direction, and placed at a greater distance from the kathode, the X-rays become less penetrative, and similar to those produced at a lower vacuum. In this way, without varying the vacuum, the penetrative value of the X-rays can be increased or decreased within limits, as desired.

Again, the author has found that the penetrative value of the X-rays can be altered by employing kathodes of different diameters. In the tube shown in Fig. 2, there are two kathodes, C and C′, both focussing upon opposite sides of the same anti-kathode B. The kathodes are of dissimilar diameter, C′ being about twice the diameter of C. If a tube of this type be exhausted to the degree necessary to give rays of medium



II

penetrative value with the smaller kathode, and the connections are then altered so as to bring the larger kathode into operation, the X-rays are immediately found to have become of very low penetrative value. If the vacuum be then increased so that, with the larger kathode in use, X-rays of medium penetrative value are obtained, it will then be found that with the smaller kathode X-rays of much higher penetrative value are produced.

In all the above-mentioned experiments the author has found that the conditions which produce X-rays of high penetrative value are also the conditions that produce a considerable potential difference between the anode and kathode portions of the tube, and at the same time a high electrical excitation of the kathode.

On the assumption that kathode rays consist of negatively charged molecules that are repelled from the similarly electrified kathode, with an initial velocity that depends upon the degree of electrical excitation of the kathode, the conditions which, as above mentioned, produce X-rays of high penetrative value, are those that would conduce to a high average velocity of the molecules at the moment at which they strike the anti-kathode, and at the same time to a high average difference of potential between the travelling molecules and the anti-kathode at the moment of impact. Conversely the conditions which produce X-rays of low penetrative value, are such as would conduce to a lower average velocity of the molecules, and to a less difference of potential between the latter and the anti-kathode.

Further, since some molecules will strike the anti-kathode at higher velocities and in a more highly-charged state than others, the same hypothesis will account for X-rays being more or less hydrogenous under all conditions.

Finally, it appears that the penetrative value, as distinct from the quantity of X-rays, is independent of the material of which the anti-kathode surface is made. The author has made experiments with tubes fitted with anti-kathodes of aluminium, iron, copper, silver, and platinum, and finds that though the metals of high atomic weight form the most efficient anti-kathodes, and give a greater quantity of X-rays, as measured by photographic action, or by the brightness of a fluorescent screen, all these metals appear to give X-rays of the same penetrative value under similar conditions.

"Condensation of Water Vapour in the presence of Dust-free Air and other Gases." By C. T. R. Wilson, M.A., Clerk-Maxwell Student in the University of Cambridge. Received March 15.

The apparatus used enabled an exceedingly rapid expansion of any desired amount to be effected. The following is a summary of the results obtained.

If air, initially saturated and free from foreign nuclei, be allowed to expand suddenly, a rainlike condensation results if the ratio of the final to the initial volume v_2/v_1 exceeds 1·252; no condensation taking place except on the walls of the vessel with smaller expansions.

The number of the drops produced remains small if v_2/v_1 does not exceed 1·37. Beyond this point the number increases at an exceedingly rapid rate with increasing expansion, the cloudlike condensation which then results showing colour phenomena of a very definite kind.

In the presence of air, oxygen, nitrogen, or carbonic acid, rainlike condensation results when the expansion is sufficient to cause the supersaturation to exceed a certain limit amounting when the final temperature is − 6° C. to between 4·2 and 4·4, and diminishing with rising temperature.

By the supersaturation is here meant the ratio of the actual density of the vapour when the expansion has just been completed, and the minimum temperature has, therefore, been reached to the density of the vapour in equilibrium over a flat surface of water at that temperature.

The condensation is cloudlike in the presence of any of these gases or of hydrogen, when the expansion is sufficient to cause the supersaturation to exceed a certain value, amounting, when the final temperature is − 16° C. to about 7·9.

When the supersaturation reached lies between these limits rainlike condensation results in all these gases, except hydrogen, in which scarcely any trace of condensation is seen when the supersaturation is even slightly below 7·9.

A statement of the effect of the Röntgen rays on condensation in the presence of air has already been published. They cause a great increase in the number of the drops produced, the minimum expansion required to cause condensation being, however, unaltered. When hydrogen is substituted for air their effect is similar, the nuclei introduced by the action of the rays requiring the supersaturation to reach the same limit as is required for rainlike condensation in air, in order that condensation may take place upon them.

Chemical Society, March 25.—Mr. A. G. Vernon Harcourt, President, in the chair.—Prof. P. Frankland delivered the Pasteur Memorial Lecture (see p. 518).

March 31.—Anniversary Meeting.—Mr. A. G. Vernon Harcourt, President in the chair.—The Longstaff medal was presented to Prof. W. Ramsay, for the discovery of helium and for his share in the investigation of argon. After the reading of the President's address, the ballot for the election of Officers and Council for the ensuing year was held.

April 1.—Prof. Dewar, President, in the chair.—The following papers were read:—The hydrolysis of perthiocyanic acid, by F. D. Chattaway and H. P. Stevens. Perthiocyanic acid is readily hydrolysed by water at 200° or by heating with strong sulphuric acid, thiourea, carbon oxysulphide and sulphur being produced; the thiourea found amongst the products of the action of strong sulphuric acid on potassium thiocyanate is certainly a product of hydrolysis of the perthiocyanic acid always produced in the reaction.—The composition of cooked fish, by Miss K. I. Williams. Determinations have been made of the constituents and heats of combustion of twenty-two species of fresh fish and five species of preserved fish and oysters after cooking. On the oxidation products of $\alpha\gamma$-dimethyl-α'-chloropyridine, by Miss E. Aston and J. N. Collie. On oxidising $\alpha\gamma$-dimethyl-α'-chloropyridine with permanganate α-chloro-γ-methyl-α'-pyridinecarboxylic acid and α-chloro-α-methyl-α'-pyridinecarboxylic acid are obtained.

Geological Society, April 7.—Dr. Henry Hicks, F.R.S., President, in the chair.—After the election of Fellows, the President left the chair, which was taken by Prof. Bonney, F.R.S.—The following communications were read:—On the Morte slates and associated beds in North Devon and West Somerset (Part ii.), by Dr. Henry Hicks, F.R.S.; with descriptions of the fossils by the Rev. G. F. Whidborne. In the first part of this paper, read by the author before the Society in February 1896, he described the Morte slates as they occurred in North Devon, and the fossils found in them. In this, the second part, he referred mainly to the rocks classified as Morte slates in West Somerset. The author contended that the Morte slates which extend through the centre of North Devon and West Somerset from Morte Point to the north of Wiveliscombe, a length of about forty miles, are the oldest rocks in the area and formed an axis with newer rocks lying to the north and to the south. In the discussion which followed the reading of the paper, Mr. Etheridge said he could not agree with the author upon the important question at issue, either as to the stratigraphical or palæontological evidence afforded by the Morte slates justifying the assertion that they were "the oldest rocks in North Devon"; and he differed entirely from the author in the conclusions drawn, as based upon this assertion. Prof. Hughes thought that, taking the difference of sediment and other circumstances which tended to modify the distribution of life, no sufficient evidence had yet been offered to establish the author's principal contention. Mr. Marr remarked that the author had established one of his main contentions, namely, that the apparent succession in North Devon was not the true one. The Rev. H. H. Winwood remarked that whatever difference may exist in the two views as to the stratigraphy of the North Devon beds, yet one fact was indisputable, that the author had found fossils in the Morte slates which previous observers had failed to do. Mr. R. S. Herries said that he had been over part of the area with the author. He had not examined the south side, but he thought that on the north there could be no doubt that on stratigraphical grounds the Treborough slates belonged to a series entirely distinct from the beds immediately north of them. Dr. J. W. Gregory referred only to the palæontological questions, and not to the stratigraphical difficulties. He said the case for the Lower Devonian age of the fauna appeared, from the evidence quoted by the author, to rest on the *Crypheus* (as the author preferred to call it) *laciniatus*. Dr. Hicks described this species as characteristically Lower Devonian; but it was commonest at the extreme top of the Lower Devonian, as in the Vichtian beds, where it was associated with Middle Devonian forms. Gosselet quoted it from the Eifelian (Middle Devonian), and asserted its occurrence in the Upper Devonian. Hence the speaker doubted whether it proved much. The author replied to the various criticisms, but held that they did not affect his conclusions.—The President then resumed the chair.—The glacio-marine drift of the Vale of Clwyd, by T. Mellard Reade. The local drift of the higher parts of the Vale of Clwyd is replaced by marine drift towards the mouth; and it was the object of this paper to give the results of a detailed examination of these marine drifts, rather than to explain the phenomena. The first part of the paper gave the results of an examination of the boulder-clay from Craig, west of Llandulas, to the Vale of Clwyd, south-east of Abergele. Mechanical analyses of the clays were given; but the point of greatest interest was the occurrence of abundance of foraminifera, especially in the plastic brown and red boulder-clays, which often contain intensely striated erratics. Mr. Strahan drew the attention of the author to Prof. Hughes's exhaustive papers on the drifts of the Vale of Clwyd. The occurrence of foraminifera was to be expected in clay so similar to that of Cheshire, in which they had long since been recorded by Mr. Shone. Prof. Hughes said that he had laid pretty fully before the Society his views as to the origin and classification of the drifts of the Vale of Clwyd (*Quart. Journ. Geol. Soc.*, vol. xliii., 1887, p. 73); and he gathered from the exposition of Mr. Mellard Reade's recent observations in that area, that the foraminifera which he had obtained all occurred in the newer or St. Asaph drift. This had all the characteristics of the shore-deposits on that coast at the present day.

Royal Meteorological Society, April 21.—Mr. E. Mawley, President, in the chair.—Mr. W. H. Dines read a paper on the relation between cold periods and anticyclonic conditions of weather in England during the winter. There seems to be a generally accepted belief that anticyclonic conditions during the winter are likely to be accompanied by exceptional cold; but, in so far as England is concerned, the author's observation has led him to the opposite conclusion, and he always expects a frost to break up as soon as the barometer gets much above 30·00 inches. To test the truth of this theory he tabulated the height of the barometer for all the cold periods during the three winter months of the fifty years 1841-90. Out of 74 frosts, he found that 16 only had a pressure exceeding 30·20 inches, and the majority of these were of very short duration. Thirty-three, or less than half, had a pressure exceeding 30·00 inches. Twenty-one had a pressure below 29·80 inches, and these included almost every frost in the period remarkable for its length or severity.—A paper by Mr. A. Lawrence Rotch, of the Blue Hill Observatory, Mass., was read, describing the use of kites at that observatory to obtain meteorological records in the upper air. Three kinds of kites have been used, viz. (1) the Malay kite, which presents a convex surface to the wind; (2) the Hargrave cellular kite; and (3) a flat kite with a fin or keel on the front, devised by Mr. Clayton. These kites are attached to a wire carrying self-recording meteorological instruments, and a steam winch automatically distributes the wire on the drum and records its pull. The instruments have been elevated more than one hundred times, and valuable meteorological data as to the changes of temperature, humidity, and wind up to an extreme altitude of 8740 feet above Blue Hill have been obtained.—A paper by Mr. A. B. MacDowall, on suggestions of sunspot influence on the weather of Western Europe, was also read. The author believes that there is a tendency to greater heat in the summer half-year, and to greater cold in the winter half-year near the phases of minimum sunspots than near the phases of maximum; the contrast between the cold and heat of the year thus tending to be intensified about the time of minimum sunspots.

PARIS.

Academy of Sciences, April 20.—M. A. Chatin in the chair.—On the classification of the Inseminæ; the subdivision of the Unitegeminæ or Icacininæ, by M. Ph. van Tieghem. A continuation of previous papers on classification.—Determination of the surface, stoutness, and chemical composition of the human body, by M. Ch. Bouchard. A series of formulæ is developed giving empirically the relations between the surface, weight, height, and girth. The factor varies with the sex, and also with the corpulency of the individual, the latter being defined by the ratio of the weight to the height.—Details of the methods employed in exact cryoscopical researches, by M. F. M. Raoult. The results of some experiments on the constancy obtainable for the convergent temperature are given, and the conclusion is drawn that it is comparatively easy to arrange matters so that the disturbing effect of the temperature of the refrigerant may be completely neutralised, the accuracy of the measurements taken with the precautions indicated being 0°·0005.—On the physiological action of the X-rays, by M. W. Crookes. The effects produced by the X-rays vary greatly with the idiosyncrasy of the experimenter, no evil effects having followed even prolonged exposure to the rays in the case of the author.—Comparison between the absorption by crystallised media of luminous rays and the Röntgen rays, by M. V.

Agafnoff. No sort of parallelism appears to exist between transparency to ultra-violet rays and the Röntgen rays, the sulphates, for example, being nearly opaque to the latter, although very transparent to the former. The reverse of this occurs with most crystallised organic compounds.—On dark light, by M. Perrigot. The results obtained by M. G. Le Bon, stated by him to be due to special rays, the "dark light," are shown to be capable of another explanation, the ebonite sheet used being itself slightly transparent to white light.—On the separation of chlorine and bromine, by MM. H. Baubigny and P. Rivals. In presence of an excess of copper salts (sulphate), bromides are totally decomposed in neutral solutions at the ordinary temperatures. The application of this method to test mixtures of chlorides and bromides gave satisfactory results.—Separation of nickel, cobalt, and iron, and of cobalt and aluminium, by M. E. Pinerua. Chloride of nickel is quite insoluble in ether saturated with hydrogen chloride, the chlorides of cobalt and iron, on the other hand, being easily soluble in this reagent. The method is sufficiently sensitive to detect the presence of nickel and iron in the "pure" cobalt chloride of commerce, and cobalt and iron in the nickel chloride sold as pure.—On cholesterine, by M. Ch. Cloëz.—On the grafting of *Helianthus annus* and *Helianthus latiflorus*, by M. L. Daniel.—The proper motion of the sun, by M. Delauney.—On a new gas battery, serving as an accumulator, by M. C. Gaudet.

DIARY OF SOCIETIES.

THURSDAY, APRIL 29.

ZOOLOGICAL SOCIETY, at 4.—Annual Meeting.
CHEMICAL SOCIETY, at 8.—Monochlordiparaconic Acid and some Condensations: Dr. H. C. Myers.—On the Decomposition of Iron Pyrites: W. A. Caldecott.
CAMERA CLUB, at 8.15.—The Automatic Telephone: S. B. Apostoloff.

FRIDAY, APRIL 30.

ROYAL INSTITUTION, at 9.—Kathode Rays: Prof. J. J. Thomson, F.R.S.
EPIDEMIOLOGICAL SOCIETY, at 8.—Some Observations on the Infectivity of Diphtheria, and its Relation to School Closure: Dr. Louis Parkes.

SATURDAY, MAY 1.

ROYAL INSTITUTION, at 5.—Annual Meeting.
GEOLOGISTS' ASSOCIATION.—Excursion to Cookham. Leave Paddington 1.40 p.m.; arrive Cookham 2.30 p.m. Director: LL. Treacher.
LONDON GEOLOGICAL FIELD CLASS.—Excursion to Leith Hill. Lower Greensand. Leave London Bridge, 2; arrive Holmwood, 3.17.

MONDAY, MAY 3.

SOCIETY OF ARTS, at 4.30.—Design in Lettering: Lewis Foreman Day.
SOCIETY OF CHEMICAL INDUSTRY, at 8.
VICTORIA INSTITUTE, at 4.30.—Nippur: its Inscriptions.
CAMERA CLUB, at 8.15.—Opening Address: Captain W. de W. Abney.—Photography at Sea: Captain Wilson Barker.

TUESDAY, MAY 4.

ROYAL INSTITUTION, at 3.—Volcanoes: Dr. Tempest Anderson.
SOCIETY OF ARTS, at 4.30.—The Arctic and Antarctic: Aubyn Trevor-Battye.
ZOOLOGICAL SOCIETY, at 8.30.—On the General Zoological Results of the Tanganyika Expedition of 1895-96: J. E. S. Moore.—On some European Slugs of the Genus *Arion*: Walter E. Collinge.—Field-Notes on the Antelopes of the Mau District, British East Africa: Frederick J. Jackson. With Notes by P. L. Sclater.
ROYAL VICTORIA HALL, at 8.30.—Mountains of Skye: Dr. T. K. Rose.
GRESHAM COLLEGE (Basinghall Street), at 6.—Planets Saturn, Uranus, and Neptune: Rev. Edmund Ledger.

WEDNESDAY, MAY 5.

SOCIETY OF ARTS, at 8.—The Railway to India: C. E. D. Black.
ENTOMOLOGICAL SOCIETY, at 8.—Homœochromatic Groups of Butterflies: Mr. Blandford.
SOCIETY OF PUBLIC ANALYSTS, at 8.—The Value of the Nitrogen Factor in the Analysis of Decomposed Milks: Alfred Smetham and J. B. Ashworth.—Notes on the Influence of Boric Acid upon the Action of Digestive Ferments: R. A. Cripps.
GRESHAM COLLEGE (Basinghall Street), at 6.—Planets Saturn, Uranus, and Neptune: Rev. Edmund Ledger.

THURSDAY, MAY 6.

ROYAL INSTITUTION, at 3.—Liquid Air as an Agent of Research: Prof. J. Dewar, F.R.S.
SOCIETY OF ARTS, at 4.30.—Kafistan: its Manners and Customs: Sir George Scott Robertson, K.C.S.I.
LINNEAN SOCIETY, at 8.
CHEMICAL SOCIETY, at 8.—A Bunsen Burner for Acetylene: A. E. Munby.—On the Reactions between Lead and the Oxides of Sulphur: H. C. Jenkins and A. E. Smith.—Ballot for Election of Fellows.
GRESHAM COLLEGE (Basinghall Street), at 6.—Planets Saturn, Uranus, and Neptune: Rev. Edmund Ledger.

FRIDAY, MAY 7.

INSTITUTION OF MECHANICAL ENGINEERS, at 7.30.—Experiments on Propeller Ventilating Fans, and on the Electric Motor driving them: William G. Walker.
GEOLOGISTS' ASSOCIATION, at 8.—Coral Islands: W. W. Watts.
GRESHAM COLLEGE (Basinghall Street), at 6.—Planets Saturn, Uranus, and Neptune: Rev. Edmund Ledger.

SATURDAY, MAY 8.

ROYAL BOTANIC SOCIETY, at 4.
GEOLOGISTS' ASSOCIATION—Excursion to Southborough and Tunbridge Wells. Director: G. Abbott. Leave Charing Cross Station (S.E.Ri) 9.22 a.m.; arrive Southborough 10.50 a.m.
LONDON GEOLOGICAL FIELD CLASS.—Excursion to Caterham to Redhill, *viâ* Godstone. Upper Greensand. Leave Cannon Street 2.17; arrive Caterham 3.12.

BOOKS, PAMPHLETS, and SERIALS RECEIVED.

BOOKS.—Queen's College, Galway, Calendar for 1896-97 (Dublin, Ponsonby).—Royal University of Ireland, Exam. Papers, 1896 (Dublin, Ponsonby).—Les Transformateurs de Tension a Courants Alternatifs: F. Loppé (Paris, Gauthier-Villars).—A Treatise on Practical Plane and Solid Geometry: T. J. Evans and W. W. F. Pullen (Chapman).—Società Reale di Napoli. THE VICTORIA UNIVERSITY.

EXTERNAL EXAMINERSHIPS.

The following External Examinerships will fall Vacant in December 1896. Each is tenable for three years, at the expiration of which the Examiner is not eligible for re-election.

Examinership.	*Retiring Examiner.*
(1) ANATOMY	Prof. ALEXANDER MACALISTER.
(2) CHEMISTRY	Prof. SYDNEY YOUNG.
(3) GEOLOGY	Prof. BONNEY.
(4) HEBREW...	Prof. RYLE.
(5) MATHEMATICS	Prof. BURNSIDE
(6) MEDICINE	Dr. THOMAS BARLOW.
(7) OBSTETRICS & DISEASES OF WOMEN... ...	Dr. CULLINGWORTH.
(8) PHYSICS	Prof. FITZGERALD.
(9) PHYSIOLOGY ...	Prof. SCHAFER.

Applications, which may be accompanied by Testimonials, should be sent in on or before November 25, 1896.

Further particulars may be obtained from

ALFRED HUGHES, Registrar.

The Victoria University, Manchester.

BALLIOL COLLEGE, CHRIST CHURCH, AND TRINITY COLLEGE, OXFORD.

NATURAL SCIENCE SCHOLARSHIPS AND EXHIBITIONS.

A Combined Examination for Natural Science Scholarships and Exhibitions will be held by the above Colleges, beginning on TUESDAY, NOVEMBER 17, 1896.

Three Scholarships and two Exhibitions will be offered, the Scholarships being worth £80 a year.

The subjects for Examination will be Physics, Chemistry, and Biology, but Candidates will not be expected to offer themselves in more than two of these.

Particulars may be obtained by application to

A. VERNON HARCOURT.

Christ Church, Oxford.

NATURAL SCIENCE SCHOLARSHIP.

KEBLE COLLEGE, OXFORD.

A SCHOLARSHIP of the annual value of £60, together with Laboratory fees, not exceeding £20 per annum, will be awarded at this College in December 1896.

The Examination commences Tuesday, December 8.

Subjects: Chemistry or Biology, with Elementary Mechanics and Physics for all Candidates, and Elementary Chemistry for those who offer Biology.

For full particulars apply to W. HATCHETT JACKSON, Keble College, Oxford.

LECTURES ON CELLULOSE AT UNIVERSITY COLLEGE.

Mr. C. F. CROSS, of the firm of CROSS and BEVAN, will deliver a Course of Fifteen Lectures, at University College, on Cellulose: the Chemistry of the Vegetable Fibres, and of their industrial preparation and uses. The Lectures will be held on Friday evenings, from 7.15 to 9.30, commencing on FRIDAY, NOVEMBER 6.

The Course will deal especially with the Cellulose Group of Carbon Compounds, thereby covering a very wide field, and will include Wood, Cotton, Peat, Lignite, Coal, Textiles, Paper, Celluloid, Artificial Silk, the Willesden Process, and other industrial applications.

Fee for Course, £1 1s. (payable by Artisans in two instalments).

QUEEN'S COLLEGES, IRELAND.

The PROFESSORSHIP OF NATURAL PHILOSOPHY in the QUEEN'S COLLEGE, BELFAST, being about to become vacant, Candidates for that Office are requested to forward their Testimonials to the Under Secretary, Dublin Castle, on or before NOVEMBER 21 next, in order that the same may be submitted to His Excellency the Lord Lieutenant.

The Candidate who may be selected for the above Professorship will have to enter upon his duties forthwith.

Dublin Castle, October 29, 1896.

LINNEAN SOCIETY OF NEW SOUTH WALES, SYDNEY.

MACLEAY BACTERIOLOGIST.

Applications for the position of Bacteriologist to the Society are invited by the Council, and must be forwarded by mail leaving London not later than December 11. Salary, £350 per annum. Full particulars on application to DULAU & Co., 37 Soho Square, London, W.

ABERYSTWYTH INTERMEDIATE SCHOOL.

The Local Governing Body are prepared to appoint a JUNIOR ASSISTANT MASTER to teach Experimental Science, at a Salary of £100 per annum. Applications, stating Age, Qualifications, and Experience, with one copy of not more than four recent Testimonials, must reach me on or before Wednesday, November 18, 1896.

SAMUEL EVANS,
Clerk to the Local Governing Body.

6 Portland Street, Aberystwyth.

THE TEACHERS' GUILD,

74 GOWER STREET, W.C.

REGISTRY DEPARTMENT FOR MEN.

SCHOLASTIC AGENCY WORK at lowest charges to cover expenses. Registrar—W. H. FRICKER, M.A., who attends daily (3 to 5 p.m. at present) except Thursdays.

MINERALS, FOSSILS, ROCKS,

NEWLY PUBLISHED CATALOGUES.

No. 5A.—Collection of 396 Crystal Models in Wood, in 32 Classes, according to Professor GROTH'S *Lehrbuch der Physikalischen Krystallographie*, 3rd Edition.

No. 11.—Collection of 280 Crystal Models in Paste-board, according to Professor URBA, Prague.

No. 12.—Collection of 102 Crystal Models in Table Glass, in 30 Classes, according to Professor RAUMHAUER, Friburg, Switzerland.

Collection of 32 Models for Tectonical Geology, according to Professor KALKOWSKY, Dresden.

My other Catalogues: I. Mineralogy (Minerals, Meteorites, Mineral Preparations for Exhibiting Optical Phenomena, Mineralogical Apparatus and Utensils). II. Palæontology and General Geology (Illustrated). IV. Rocks, Thin Sections of Rocks, Petrographical Apparatus and Utensils.

Will be supplied Gratis on Application.

Dr. F. KRANTZ,

Rhenish Mineral Office, Bonn on the Rhine.

ESTABLISHED 1833.

INDUCTION COILS.

Messrs. NEWTON & CO., of 3 FLEET STREET, LONDON, have made an arrangement with Mr. APPS by which the results of his unequalled experience in large Coil making have been fully placed at their disposal.

As he has been unable to cope with the demand for these instruments, Apps' Patented Coils are now manufactured concurrently by Messrs. NEWTON & Co. on their own premises.

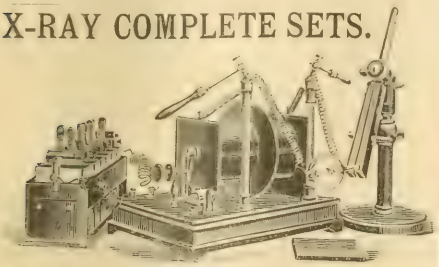
These Coils have for many years been acknowledged the best and most efficient in the world, and it is hoped that the high quality of workmanship maintained in Messrs. NEWTON & Co.'s workshops may still further increase their reputation.

All the Coils up to 10-inch are tested to considerably more than the guaranteed length of spark.

Spark in air.	£	s.	d.	Spark in air.	£	s.	d.
1 in.	5	5	0	8 in. (with pillars)	27	10	0
2 ,, ...	10	10	0	10 ,, ,, ,,	36	15	0
3 ,, ...	12	12	0	15 ,, ,, ,,	63	0	0
4 ,, ...	15	15	0	18 ,, ,, ,,	75	0	0
6 ,, (with pillars)	22	10	0	Larger sizes to order.			

All the above Coils are covered in ebonite, and are of the highest quality, and all are fitted with Commutator and five pairs of Terminals so that they can be used with Primary Batteries or Accumulators or direct from the main, and the Condenser can be cut out if desired, which should be done when using alternate currents.

X-RAY COMPLETE SETS.



SET A. Including 3-inch Coil, our own make, Batteries, Focus Tube, Tube Holder, Barium-Platino-Cyanide Screen, 7 in. × 5 in. £13 0 0

SET B. Including 6-inch Coil, Batteries, Larger Focus Tube, Tube Holder, Barium-Platino-Cyanide Screen, 9½ in. × 7 in. £23 10 0

BARIUM-PLATINO-CYANIDE SCREENS.

EXCELLENT FLUORESCENCE, in neat Frames with Handles.

INSTITUTE OF CHEMISTRY OF GREAT BRITAIN AND IRELAND,

30 BLOOMSBURY SQUARE, LONDON, W.C.

The NEXT EXAMINATIONS for the MEMBERSHIP of this INSTITUTE will be held on TUESDAY, January 12, 1897, and three following days.

In consequence of the increase in the number of Candidates whose applications for Examination have been accepted by the Council, it is probable that more than the two ordinary Examinations (January and July) may be held in 1897.

Application forms can be obtained from the Secretary at the above address.

All Candidates must produce evidence of having passed a Preliminary Examination in subjects of General Education, and of having taken a Systematic Course of at least three years' study in one of the Colleges approved by the Council; or, of having been engaged for two years in the Laboratory of a Fellow of the Institute, and for two other years in one of the approved Colleges.

The Council desire it to be understood that the right to use the letters A.I.C. and F.I.C. belongs to persons who have passed through the Course of Study and the Examinations prescribed by the Institute.

A Prospectus, containing full particulars of the regulations for admission to the Membership of the Institute, may be obtained from Messrs. BLUNDELL, TAYLOR, & Co., 173 Upper Thames Street, London, E.C., price One Shilling.—By Order of the Council,

J. MILLAR THOMSON, Registrar.

ROYAL SCOTTISH SOCIETY OF ARTS,

117 GEORGE STREET, EDINBURGH.

LIST of PRIZES offered by the SOCIETY for PAPERS submitted during the Session 1896-97.

(1) A KEITH PRIZE, value 30 Sovereigns, for some important Invention, Improvement, or Discovery in the Useful Arts, primarily submitted to the Society during the Session.

(2) A HEPBURN PRIZE, value 12 Sovereigns, for such Invention or Communication submitted to the Society as shall be approved of by the Society or its Prize Committee.

(3) A MARDOUGALL-BRISBANE PRIZE, value 10 Sovereigns, for such Communication of Merit or such Invention as shall be approved of by the Society or its Prize Committee.

(4) A REID and AULD PRIZE, value about 7 Sovereigns, for any Novelty in the Art of Clock or Watch Making, if such should be considered worthy of a Prize.

For further information with regard to these Prizes and conditions, apply to the Secretary, who is now prepared to receive Communications for next Session.

WM. ALLAN CARTER, C.E., Secretary.

for SALE.—A complete Set, including Narrative of the Voyage, Deep Sea Deposits, and Summary of Results. Forty-six large quarto Volumes, as published, offered at £60.—Apply to "MARINER," NATURE Office.

FOR SALE, Maximum and Minimum

Thermometers, Hygrometer (Wet and Dry Bulbs), Kew tested, Stevenson's Screen and Rain Gauge. Never been used. Bargain.—FRONSHAM, 3 Harpur Street, Bedford.

SPECTROSCOPE.

WANTED, to Purchase, Second-Hand, a Spectroscope, with two to four Prisms. State Price and Maker's name.
Address, "N.," 4 Branstone Road, Kew Gardens.

ZOOLOGICAL SPECIMENS FOR DISSECTION.

All types required for Science Courses, perfect condition guaranteed
The following are some of the chief forms, with prices:

Scyllium, 10*d*. each; 8*s*. doz.
Amphioxus, 9*d*. each.
Astacus, 9*d*. each.
Anodon, 9*d*. each.
Rana, 6*d*. each.

Noctiluca, 1*s*. 3*d*. per tube.
Grantia, 1*s*. 3*d*. per tube.
Sycon, 1*s*. 3*d*. per tube.
Medusoids, 1*s*. 3*d*. per tube.
Aurelia, 10*d*. each.
Coryne, 1*s*. per tube.
Obelia, 1*s*. per tube.
Ascaris (large), 8*d*. each.
Cerebratulus, 1*s*. 6*d*. each.
Nereis, 6d. each.
Arenicola, 6d. each.
Sagitta, 1*s*. per tube.

Sipunculus, 3*s*. to 4*s*. doz.
Echinus (large), 10*s*. doz.
Cucumaria (large), 1*s*. 4*d*. each.
Apus, 1*s*. each.
Nebalia, 1*s*. per tube.
Gammarus, 1*s*. per tube.
Scorpio, 1*s*. to 1*s*. 6*d*. each.
Scolopendra, 1*s*. 6*d*. each.
Aplysia, 8*d*. to 10*d*. each.
Haliotis, 8*d*. each.
Loligo media, 10*d*. each.
Mya, 10*d*. each.
Pedicellina. 1*s*. per tube.
Salpa, 1*s*. 6*d*. per tube.
Ascidia, 8d. each.
Raia, 1*s*. to 2*s*. 6*d*. each.
Lacerta, 10*d*. each.

REDUCTION ON LARGER QUANTITIES.

JAMES HORNELL, BIOLOGICAL STATION, JERSEY.

LIVING SPECIMENS FOR THE MICROSCOPE.

Volvox, Spirogyra, Desmids, Diatoms, Amœba, Arcella, Actinosphærium, Vorticella, Stentor, Hydra, Floscularia, Stephanoceros, Melicerta, and many other Specimens of Pond Life. Price 1*s*. per Tube, Post Free. Helix pomatia, Astacus, Amphioxus, Rana, Anodon, &c., for Dissection purposes.

THOMAS BOLTON,

25 BALSALL HEATH ROAD, BIRMINGHAM.

MARINE BIOLOGICAL ASSOCIATION OF THE UNITED KINGDOM.

THE LABORATORY, PLYMOUTH.

The following animals can always be supplied, either living or preserved by the best methods:—

Sycon; Clava, Obelia, Sertularia; Actinia, Tealia, Caryophyllia, Alcyonium; Hormiphora (preserved); Leptoplana; Lineus, Amphiporus; Nereis, Aphrodite, Arenicola, Lanice, Terebella; Lepas, Balanus, Gammarus, Ligia, Mysis, Nebalia, Carcinus; Patella, Buccinum, Eledone, Pectens Bugula, Crisia, Pedicellina; Holothuria, Asterias, Echinus; Ascidia, Salpa (preserved), Scyllium, Raia, &c., &c.

For prices and more detailed lists apply to Biological Laboratory, Plymouth.

INDUCTION COILS.

Messrs. NEWTON & CO., of 3 FLEET STREET, LONDON, have made an arrangement with Mr. APPS by which the results of his unequalled experience in large Coil making have been fully placed at their disposal.

As he has been unable to cope with the demand for these instruments, Apps' Patented Coils are now manufactured concurrently by Messrs. NEWTON & CO. on their own premises.

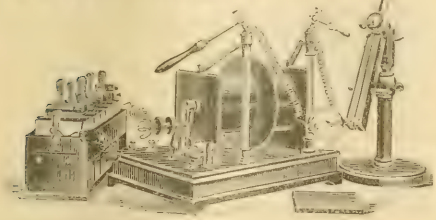
These Coils have for many years been acknowledged the best and most efficient in the world, and it is hoped that the high quality of workmanship maintained in Messrs. NEWTON & CO.'s workshops may still further increase their reputation.

All the Coils up to 10-inch are tested to considerably more than the guaranteed length of spark.

Spark in air.	£	s.	d.	Spark in air.	£	s.	d.
1 in.	5	5	0	8 in. (with pillars)	27	10	0
2 ,, ...	10	10	0	10 ,, ,, ,,	36	15	0
3 ,, ...	12	12	0	15 ,, ,, ,,	63	0	0
4 ,, ...	15	15	0	18 ,, ,, ,,	75	0	0
6 ,, (with pillars)	22	10	0	Larger sizes to order.			

All the above Coils are covered in ebonite, and are of the highest quality, and all are fitted with Commutator and five pairs of Terminals so that they can be used with Primary Batteries or Accumulators or direct from the main, and the Condenser can be cut out if desired, which should be done when using alternate currents.

X-RAY COMPLETE SETS.



SET A. Including 3-inch Coil, our own make, Batteries, Focus Tube, Tube Holder, Barium-Platino-Cyanide Screen, 7 in. × 5 in. £13 0 0

SET B. Including 6-inch Coil, Batteries, Larger Focus Tube, Tube Holder, Barium-Platino-Cyanide Screen, 9½ in. × 7 in. £23 10 0

BARIUM-PLATINO-CYANIDE SCREENS.

EXCELLENT FLUORESCENCE, in neat Frames with Handles. 7 in. × 5 in., 21s.; 9½ in. × 7 in., 32s. 6d.; 11¾ in. × 9½ in., 55s.

Prof. HENRY A. MIERS, M.A., F.R.S. Three Lectures on "Some Secrets of Crystals." On Thursdays, January 21, 28, February 4. Half-a-Guinea.

J. W. GREGORY, Esq., D.Sc., F.G.S., of the British Museum (Natural History). Three Lectures on "The Problems of Arctic Geology. On Thursdays, February 11, 18, 25. Half-a-Guinea.

Prof. PERCY GARDNER, Litt.D., F.S.A., Professor of Classical Archæology and Art in the University of Oxford. Three Lectures on "Greek History and Extant Monuments." On Thursdays, March 4, 11, 18. Half-a-Guinea.

Prof. W. BOYD DAWKINS, M.A., F.R.S., F.S.A., F.G.S. Three Lectures on "The Relation of Geology to History." 1. The Incoming of Man. 2. The Frontier of History in Britain. 3. Roman Britain. On Thursdays, March 25, April 1, 8. Half-a-Guinea.

CARL ARMBRUSTER, Esq. Three Lectures on "Neglected Italian and French Composers." (With Musical Illustrations.) On Saturdays, January 23, 30, February 6. Half-a-Guinea.

WALTER FREWEN LORD, Esq. Three Lectures on "The Growth of the Mediterranean Route to the East." On Saturdays, February 13, 20, 27. Half-a-Guinea

The Right Hon. LORD RAYLEIGH, M.A., D.C.L., LL.D., F.R.S., *M.R.I.*, Professor of Natural Philosophy, R.I. Six Lectures on "Electricity and Electrical Vibrations." On Saturdays, March 6, 13, 20, 27, April 3, 10. One Guinea.

Subscription (to Non-Members) to all Courses of Lectures (extending from Christmas to Midsummer), Two Guineas. Tickets issued daily at the Institution, or sent by post on receipt of Cheque or Post-Office Order.

Members may purchase not less than Three Single Lecture Tickets, available for any Afternoon Lecture, for Half-a-Guinea.

The Friday Evening Meetings will begin on January 22 at 9 p.m., when Prof. DEWAR will give a Discourse on "Properties of Liquid Oxygen." Succeeding Discourses will probably be given by the Right Rev. The LORD BISHOP OF LONDON, Prof. JAGADIS CHUNDER BOSE, Prof. JOHN MILNE, Dr. G. JOHNSTONE STONEY, Lieut.-Colonel C. R. CONDER, Mr. SHELFORD BIDWELL, Prof. ARTHUR SMITHELLS, Sir EDWARD MAUNDE THOMPSON, K.C.B., Sir WILLIAM TURNER, Mr. CHARLES T. HEYCOCK, The Right Hon. LORD RAYLEIGH, and other gentlemen. To these Meetings Members and their Friends only are admitted.

Persons desirous of becoming Members are requested to apply to the SECRETARY. When proposed they are immediately admitted to all the Lectures, to the Friday Evening Meetings, and to the Library and Reading Rooms; and their Families are admitted to the Lectures at a reduced charge. Payment: First Year, Ten Guineas; afterwards, Five Guineas a Year; or a composition of Sixty Guineas.

BEDFORD COLLEGE, LONDON (FOR WOMEN),

YORK PLACE, BAKER STREET, W.

Principal: Miss EMILY PENROSE.

SESSION 1896-7.

The LENT TERM will BEGIN on THURSDAY, JANUARY 14.

Courses in preparation for all the Examinations in the Faculties of Arts and Science held by the University of London. Special Course of Scientific Instruction in Hygiene and Public Health.

Lectures in all branches of Higher Education. Six Laboratories open to Students for Practical Work. Art School open from 10 to 4. Students can reside in the College.

LUCY J. RUSSELL, Honorary Secretary.

THE TEACHERS' GUILD,

[All Rights are Reserved.

INDUCTION COILS.

Messrs. NEWTON & CO., of 3 FLEET STREET, LONDON, have made an arrangement with Mr. APPS by which the results of his unequalled experience in large Coil making have been fully placed at their disposal.

As he has been unable to cope with the demand for these instruments, Apps' Patented Coils are now manufactured concurrently by Messrs. NEWTON & Co. on their own premises.

These Coils have for many years been acknowledged the best and most efficient in the world, and it is hoped that the high quality of workmanship maintained in Messrs. NEWTON & Co.'s workshops may still further increase their reputation.

All the Coils up to 10-inch are tested to considerably more than the guaranteed length of spark.

Spark in air.	£	s.	d.	Spark in air.	£	s.	d.
1 in.	5	5	0	8 in. (with pillars)	27	10	0
2 ,, ...	10	10	0	10 ,, ,, ,,	36	15	0
3 ,, ...	12	12	0	15 ,, ,, ,,	63	0	0
4 ,, ...	15	15	0	18 ,, ,, ,,	75	0	0
6 ,, (with pillars)	22	10	0	Larger sizes to order.			

All the above Coils are covered in ebonite, and are of the highest quality, and all are fitted with Commutator and five pairs of Terminals so that they can be used with Primary Batteries or Accumulators or direct from the main, and the Condenser can be cut out if desired, which should be done when using alternate currents.

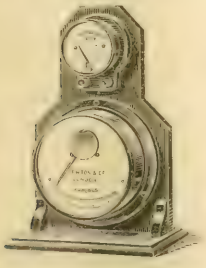
NEWTONIAN X-RAY CURRENT METER.



The principal difficulty in "X" Ray photography has been to judge the length of exposure. This can easily be done by fusing an ammeter and voltmeter permanently in the circuit. The arrangement answers the purpose admirably. The same conditions can, if desired, be reproduced from day to day, and the voltage being constant, the number of amperes, on which the rapidity of exposure then entirely depends, can be varied as desired and adjusted to the greatest nicety by the tension screw of the coil.

"X" Ray Current Meter, comprising Ammeter and Voltmeter suitable for use with Induction Coils, £5 5s.

BRITISH ASSOCIATION FOR THE ADVANCEMENT OF SCIENCE,

BURLINGTON HOUSE, LONDON, W.

The NEXT ANNUAL MEETING of the ASSOCIATION will be held at TORONTO, CANADA, commencing on WEDNESDAY, AUGUST 18, 1897.

PRESIDENT-ELECT:

SIR JOHN EVANS, K.C.B., D.C.L., Treasurer of the Royal Society.

Information about local arrangements may be obtained from the SECRETARIES, Toronto, or at the London Office.

G. GRIFFITH, Assistant General Secretary.

BEDFORD COLLEGE, LONDON (FOR WOMEN),

YORK PLACE, BAKER STREET, W.

Principal: Miss EMILY PENROSE.

SESSION 1896–7.

The LENT TERM will BEGIN on THURSDAY, JANUARY 14.

Courses in preparation for all the Examinations in the Faculties of Arts and Science held by the University of London. Special Course of Scientific Instruction in Hygiene and Public Health.

Lectures in all branches of Higher Education. Six Laboratories open to Students for Practical Work. Art School open from 10 to 4. Students can reside in the College.

LUCY J. RUSSELL, Honorary Secretary.

THE ELECTRICAL AND GENERAL ENGINEERING COLLEGE, AND SCHOOL OF SCIENCE.

PENYWERN HOUSE, 2 and 4, PENYWERN ROAD, EARL'S COURT, S.W.

PRINCIPAL—G. W. DE TUNZELMANN, B.Sc., M.I.E.E.
SENIOR-INSTRUCTOR—C. CAPITO, M.I.E.E., M.I.M.E.

Laboratories, Dynamo Room, Steam Engine, Engineering Workshop with Machine Tools, Pattern Shop, &c.

The College provides a Training for Electrical, Mechanical, Civil, and Mining Engineers, for Science Students in Mathematics, Physics, Chemistry, Biology, Geology, and Mineralogy, and Preliminary Training for Students entering Cooper's Hill and the Central Institution.

CIVIL SERVICE COMMISSION FORTHCOMING EXAMINATION.

JUNIOR ASSISTANT in the Art Branch of the South Kensington Museum (18-25), January 28. The date specified is the latest at which Applications can be received. They must be made on Forms to be obtained, with particulars, from the SECRETARY, Civil Service Commission, London, S.W.

THE TEACHERS' GUILD,

74 GOWER STREET, W.C.

REGISTRY DEPARTMENT FOR MEN.

SCHOLASTIC AGENCY WORK at lowest charges to cover expenses. Registrar—W. H. FRICKER, M.A., who attends daily (3 to 5 p.m. at present) except Thursdays.

KING'S COLLEGE, LONDON.

GEOLOGY.

Prof. SEELEY, F.R.S., will resume his Evening Lectures in the Faculty of Science, on Mondays, Tuesdays, and Thursdays, beginning January 21, 1897. Further particulars at the Office of the College.

WALTER SMITH, Secretary.

TRAVELLER'S ALTAZIMUTH

(CASELLA'S).—Altitude Instrument, Optical Compass, Clinometer, and Level, in one Instrument; perfect condition. Cost £6 6s.; half-price.—"L. K.," Conservative Club, Gloucester.

OPTICAL & SCIENTIFIC INSTRUMENTS.

Spectrometers, Spectroscopes, Goniometers, Cathetometers, Optical Benches, &c., &c. Instruments for special purposes constructed to Clien s' own designs. *Price List on application.*

W. WILSON (formerly Foreman at Messrs. ELLIOTT BROS.), 56 Crogsland Road, Chalk Farm, London, N.W.

MANUFACTURER OF
ELECTRICAL & PHYSICAL INSTRUMENTS,
44 Hatton Garden, London.

ALFRED JÖRGENSEN'S LABORATORY FOR THE PHYSIOLOGY AND TECHNOLOGY OF FERMENTATION.

COPENHAGEN, V. (ESTABLISHED 1881.)

STUDENTS' SESSIONS.—Courses of Instruction in the Physiology and Technology of Fermentation for Beginners and Advanced Students, with particular regard to HANSEN'S System for the Pure Cultivation and Analysis of Yeast and the application of selected pure Yeast types in practice.

(1) Mould-fungi. (2) Forms of Transition between Mould-fungi and Saccharomyces Yeast-fungi. (3) Yeast-fungi: Culture Yeast Types, Wild Yeasts, Disease Yeast. (4) Fermentation Bacteria. (5) Preparation of absolutely pure Cultures of Yeast-fungi. (6) Preparation of Cultures on a large scale. (7) Comparative Experiments with Mass Culture, and Instruction in their Use in Practice (in Breweries, Distilleries, Wine Fermentation, &c.). (8) Supervision of Fermentation Establishments. (9) Preservation of Selected Types of Yeast. (10) Instruction in the Use of Yeast Propagating Machines.

The English, French, Danish and German languages are used in the instruction.

The Laboratory possesses a numerous collection of Culture-Yeast Types (for Breweries, Distilleries, Grape Wine, Fruit Wine), Wild Yeasts (Disease Yeast), and Fermentation Bacteria, all of which are supplied for use in Laboratories and in practice.

Manuals of Instruction:—Alfred Jörgensen: "Micro-Organisms and Fermentation," new edition, 1893 (published by F. W. Lyon, Eastcheap Buildings, London). French Edition (Société d'Editions Scientifiques, Paris, 1894). Third German Edition (P. Parey, Berlin, 1892).

E. Chr. Hansen: "Practical Studies in Fermentation (Contributions to the Life-history of Micro-Organisms)" (E. F. Spon, London, 1895). French Résumé in the "Comptes rendus du Laboratoire de Carlsberg" (Hagerup, Copenhagen). German Edition (R. Oldenbourg, Munich, 1890-1895))

Prospectus gratis on application.

The Laboratory has up to this day been frequented by 380 Students from all countries, among them by 41 English and American Students.

MINERALS, FOSSILS, ROCKS.

COLLECTIONS OF THIN SLICES FOR PRACTICAL MICROSCOPIC PETROGRAPHICAL STUDY.

These Collections contain thin Slices of all of the more important Types of Rocks, as mentioned in the latest edition of the "Microscopic Physiography of Rocks," by H. Rosenbusch (Stuttgart, 1896).

To each one will be added a printed short description of all the Specimens and Slices, in order that the student himself might be able to recognise and determine the constituents of the Rock.

Collections of 120, 180, and 250 Thin Slices. Price, in Elegant Cases, £7 10s., £11 5s., £16 5s., respectively.

The same Collections, inclusive of the Specimens (size, 3½ × 4½ inches), £12 10s., £19 10s., £28 15s., respectively.

As all thin Slices will be microscopically examined before being delivered, we can guarantee their perfect reliability, and that they exhibit all the characteristics of the rocks, as mentioned in the above-named description.

Dr. F. KRANTZ,

Bonn on Rhine. Rhenish Mineral Office.

ESTABLISHED 1833.

(Represented by Messrs. HARRINGTON BROS., Oliver's Yard, 53A City Road, London, E.C.; and Cork, Ireland.)

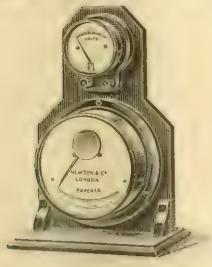
NEWTONIAN X-RAY CURRENT METER.



The principal difficulty in X-Ray photography has been to judge the length of exposure. This can easily be done by using an X-Ray Current Meter. The arrangement answers the purpose admirably. The same conditions can, if desired, be reproduced from day to day, and the voltage being constant, the number of amperes, on which the rapidity of exposure then entirely depends, can be varied as desired and adjusted to the greatest nicety by the tension screw of the coil.

"X" Ray Current Meter, comprising Ammeter and Voltmeter suitable for use with Induction Coils, £5 5s.

Sole Makers:

NEWTON & CO.

3 FLEET STREET, LONDON.

List of Apps-Newton Induction Coils and X-Ray Apparatus Post Free on application.

THE DAVY FARADAY RESEARCH LABORATORY OF THE ROYAL INSTITUTION.

DIRECTORS:
The Right Hon. LORD RAYLEIGH, M.A., D.C.L., LL.D., F.R.S.
Prof. DEWAR, M.A., LL.D., F.R.S.
SUPERINTENDENT OF THE LABORATORY:
Dr. ALEXANDER SCOTT, M.A., D.Sc.

This Laboratory, which has been founded by Dr. Ludwig Mond, F.R.S., as a Memorial of Davy and Faraday, "for the purpose of promoting original research in Pure and Physical Chemistry," will be open on January 18.

Under the Deed of Trust, workers in the Laboratory are entitled, free of charge, to Gas, Electricity and Water, as far as available, and, at the discretion of the Directors, to the use of the apparatus belonging to the Laboratory, together with such materials and chemicals as may be authorised.

All persons desiring to be admitted as workers, must send evidence of scientific training, qualification, and previous experience in original research, along with a statement of the nature of the investigation they propose to undertake. Further information, together with forms of application, can be had from the ASSISTANT SECRETARY, Royal Institution.

ROYAL INSTITUTION OF GREAT BRITAIN.

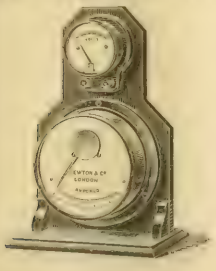
NEWTONIAN X-RAY CURRENT METER.



The principal difficulty in X-Ray photography has been to judge the length of exposure. This can easily be done by using an X-Ray Current Meter. The arrangement answers the purpose admirably. The same conditions can, if desired, be reproduced from day to day, and the voltage being constant, the number of amperes, on which the rapidity of exposure then entirely depends, can be varied as desired and adjusted to the greatest nicety by the tension screw of the coil.

"X" Ray Current Meter, comprising Ammeter and Voltmeter suitable for use with Induction Coils, £5 5s.

SOLE MAKERS:

NEWTON & CO.

3 FLEET STREET, LONDON.

List of Apps-Newton Induction Coils and X-Ray Apparatus Post Free on application.

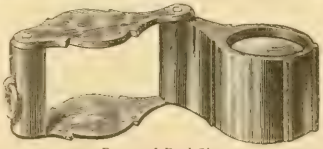
BROWNING'S PLATYSCOPIC LENS.

With Larger Angles, Increased Field, and Improved Definition.



Engraved Real Size.

AN ACHROMATIC COMBINATION,

COMBINING THE DEFINITION OF A MICROSCOPE WITH THE PORTABILITY OF A POCKET LENS.

"If you carry a small Platyscopic Pocket Lens (which every observer of Nature ought to do)."—GRANT ALLEN in *Knowledge*.

The Platyscopic Lens is invaluable to botanists, mineralogists, or entomologists, as it focuses about three times as far from the object as the Coddington Lenses. This allows opaque objects to be examined easily.

The Platyscopic Lens is made of four degrees of power, magnifying respectively 10, 15, 20, and 30 diams., the lowest power, having the largest field, is the best adapted for general use.

The Lenses are set in Ebonite Cells, and mounted in Tortoiseshell Frames.

Price of the Platyscopic Lens, mounted in Tortoiseshell, magnifying either 10, 15, 20, or 30 diameters, 18s. 6d. each power.

Illustrated description sent free.

JOHN BROWNING, 63 STRAND, LONDON, W.C.

NEGRETTI AND ZAMBRA'S BAROGRAPHS AND THERMOGRAPHS.

The Barograph is fitted in a Mahogany Case with Glass Front, as shown above. The Thermograph is mounted in a japanned Metal Case with Glass Front, for either indoor or outdoor use. The above give continuous records which only require changing once a week, and are invaluable to Invalids and others who are unable to take daily readings of the ordinary instruments. Price of each, with supply of Charts for one year, £6 10s.

GUY'S HOSPITAL MEDICAL SCHOOL.

The SUMMER SESSION will begin on May 3, and Students then entering will be eligible to compete for Entrance Scholarships of the combined value of £360 in the following September; as well as for the numerous Medals, Scholarships and Prizes, awarded during the period of Studentship.

H.R.H. THE PRINCE OF WALES has intimated his intention of formally opening early in the Session the recently erected Laboratories, Lecture Theatre, and Class Rooms, which will form a most valuable addition to the teaching resources of the School.

The number of Patients treated in the Wards during last year exceeded 6000, and the Governors have announced that between 30 and 40 additional Beds will be immediately provided for the reception of Maternity Cases, and of Patients suffering from Diseases peculiar to Women.

The Appointments tenable by Students have recently been increased by more than 150 a year chiefly by the addition of Clerkship and Dresserships in the departments of Ophthalmology, Gynæcology, and Otology.

To augment the teaching of special subjects, Registrars and Tutors have been appointed in the Ophthalmic and Obstetric Departments.

All Hospital Appointments are open to Students without charge, and the holders of Resident Appointments are provided with board and lodging.

The College accommodates 60 Students, under the supervision of a Resident Warden.

The Dental School provides the full Curriculum required for the L.D.S. England.

The Clubs Union Athletic Ground is easily accessible.

A Handbook of Information for those about to enter the Medical Profession will be forwarded on application.

For the Prospectus of the School, containing full particulars as to Fees, Course of Study advised, Regulations for residence in the College, &c., apply, personally or by letter, to the DEAN, Guy's Hospital, London Bridge, S.E.

THE LONDON HOSPITAL MEDICAL COLLEGE.

The SUMMER SESSION commences on May 1.

The Hospital is the largest in the kingdom; nearly 800 beds are in constant use.

APPOINTMENTS.—House Physicians, House Surgeons, &c.—Sixty of these Appointments are made annually. Dressers, Clinical Clerks, &c., appointed every three months. All are free to Students of the College. Holders of Resident Appointments have Free Board.

SCHOLARSHIPS AND PRIZES.—Twenty-seven Scholarships and Prizes are given annually. Students entering in May can compete for the Entrance Scholarships in September.

Special arrangements have been made to enable Students entering in May to present themselves for Examination in Chemistry, &c., in July.

Special Classes are held for the University of London Examinations. Special entries for Medical and Surgical Practice can be made.

A reduction of 15 guineas is made to the Sons of Members of the Profession.

The Metropolitan and other Railways have Stations close to the Hospital and College.

For further information apply, personally or by letter, to

Mile End, E. MUNRO SCOTT, Warden.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, S.E.

The SUMMER SESSION will commence on MONDAY, May 3. Students entering in the Summer are eligible to compete for the Science Scholarships of £150 and £60 awarded in October.

A Scholarship of £50, open to University Students, and other Prizes and Scholarships of the value of £500, are offered for annual competition.

All Appointments are open to Students without extra payment.

Special Classes for the Examinations of the University of London are held throughout the year.

Tutorial Classes are held prior to the Second and Final Examinations of the Conjoint Board in January, April, and July.

A Register of approved lodgings and of private families receiving Boarders is kept in Secretary's Office.

Excellent Day Club accommodation is provided in the School Building.

Prospectuses and all particulars may be obtained from the Medical Secretary, Mr. G. RENDLE.

THE DAVY FARADAY RESEARCH LABORATORY OF THE ROYAL INSTITUTION.

DIRECTORS:

The Right Hon. LORD RAYLEIGH, M.A., D.C.L., LL.D., F.R.S.

Professor DEWAR, M.A., LL.D., F.R.S.

SUPERINTENDENT OF THE LABORATORY:
Dr. ALEXANDER SCOTT, M.A., D.Sc.

This Laboratory, which has been founded by Dr. Ludwig Mond, F.R.S., as a Memorial of Davy and Faraday "for the purpose of promoting original research in Pure and Physical Chemistry," is now open. The next Term begins on May 3, 1897.

Under the Deed of Trust, workers in the Laboratory are entitled, free of charge, to Gas, Electricity and Water, as far as available, and, at the discretion of the Directors, to the use of the apparatus belonging to the Laboratory, together with such materials and chemicals as may be authorised.

All persons desiring to be admitted as workers, must send evidence of scientific training, qualification, and previous experience in original research, along with a statement of the nature of the investigation they propose to undertake. Further information, together with forms of Application, can be had from the ASSISTANT SECRETARY, Royal Institution.

CENTRAL WELSH BOARD FOR INTERMEDIATE EDUCATION.

EXAMINATION OF SCHOOLS, 1897.

APPOINTMENT OF CHIEF EXAMINERS.

The Executive Committee of the Central Welsh Board will shortly proceed to the appointment of Five Chief Examiners.

Candidates must have special knowledge of at least one of the following Departments:—

1. CLASSICS.
2. MATHEMATICS.
3. ENGLISH LANGUAGE AND LITERATURE.
4. WELSH LANGUAGE AND LITERATURE.
5. HISTORY.
6. MODERN LANGUAGES.
7. PHYSICS.
8. CHEMISTRY.
9. BOTANY.

Candidates are requested to send in their Applications not later than the 30th day of April next, to the undersigned, from whom further particulars may be obtained.

OWEN OWEN, Chief Inspector.

Oswestry, March 25, 1897.

GOVERNMENT OF WESTERN AUSTRALIA.

Applications are invited for the Position of ASSISTANT GEOLOGIST, at a Salary of £300 per annum, and actual travelling and incidental expenses incurred.

The Applications, accompanied by Testimonials (copies in the first instance), and an account of the Candidate's experience in Geology and Mining, to be lodged with the undersigned not later than June 30, 1897.

NEGRETTI AND ZAMBRA'S
BAROGRAPHS AND THERMOGRAPHS.

The Barograph is fitted in a Mahogany Case with Glass Front, as shown above. The Thermograph is mounted in a japanned Metal Case with Glass Front, for either indoor or outdoor use. The above give continuous records on Charts, which only require changing once a week, and are invaluable to invalids and others who are unable to take daily readings of the ordinary instruments. Price of each, with supply of Charts for one year, £6 10s.

Branches: 45 CORNHILL, and 122 REGENT STREET.

GUY'S HOSPITAL MEDICAL SCHOOL.

The SUMMER SESSION will begin on May 3, and Students then entering will be eligible to compete for Entrance Scholarships of the combined value of £360 in the following September, as well as for the numerous Medals, Scholarships and Prizes, awarded during the period of Studentship.

H.R.H. THE PRINCE OF WALES has intimated his intention of formally opening early in the Session the recently erected Laboratories, Lecture Theatre, and Class Rooms, which will form a most valuable addition to the teaching resources of the School.

The number of Patients treated in the Wards during last year exceeded 6000, and the Governors have announced that between 30 and 40 additional Beds will be immediately provided for the reception of Maternity Cases, and of Patients suffering from Diseases peculiar to Women.

The Appointments tenable by Students have recently been increased by more than 150 a year chiefly by the addition of Clerkship and Dresserships in the departments of Ophthalmology, Gynæcology, and Otology.

To augment the teaching of special subjects, Registrars and Tutors have been appointed in the Ophthalmic and Obstetric Departments.

All Hospital Appointments are open to Students without charge, and the holders of Resident Appointments are provided with board and lodging.

The College accommodates 60 Students, under the supervision of a Resident Warden.

The Dental School provides the full Curriculum required for the L.D.S. England.

The Clubs Union Athletic Ground is easily accessible.

A Handbook of Information for those about to enter the Medical Profession will be forwarded on application.

For the Prospectus of the School, containing full particulars as to Fees, Course of Study advised, Regulations for residence in the College, &c., apply, personally or by letter, to the DEAN, Guy's Hospital, London Bridge, S.E.

ST. THOMAS'S HOSPITAL MEDICAL SCHOOL,

ALBERT EMBANKMENT, S.E.

The SUMMER SESSION will commence on MONDAY, May 3. Students entering in the Summer are eligible to compete for the Science Scholarships of £150 and £60 awarded in October.

A Scholarship of £50, open to University Students, and other Prizes and Scholarships of the value of £500, are offered for annual competition.

All Appointments are open to Students without extra payment.

Special Classes for the Examinations of the University of London are held throughout the year.

Tutorial Classes are held prior to the Second and Final Examinations of the Conjoint Board in January, April, and July.

A Register of approved lodgings and of private families receiving Boarders is kept in Secretary's Office.

Excellent Day Club accommodation is provided in the School Building.

Prospectuses and all particulars may be obtained from the Medical Secretary, Mr. G. RENDLE.

H. P. HAWKINS, M.A., M.D., Oxon., Dean.

LONDON HOSPITAL MEDICAL COLLEGE.

The SUMMER SESSION Commences on May 1.

Students entering then are eligible to compete for the Entrance Scholarships in September and October. Twenty-seven Scholarships and Prizes are offered annually.

Special arrangements are made to meet the requirements of Students entering in the Summer Session.

A reduction of 15 Guineas is allowed to the Sons of Members of the Profession.

For Prospectus and full particulars apply to

MUNRO SCOTT, Warden.

Mile End, E.

UNIVERSITY COLLEGE, LONDON.
